**National Insurance.**—Mr. Groves asked the Minister of Health, on June 23rd, if he was aware that his officers connected with national health insurance had recently decided to charge against the funds of Local Insurance Committees the cost of investigating excessive prescribing, and that these investigations were carried out for the purposes of his department; and whether he would arrange for the necessary expenses incurred to be borne by his department and not imposed upon the Local Insurance Committees. Sir Kingsley Wood replied that there had been any change of policy in this matter. It was always intended that the cost of these investigations should be met from the funds available for the administration expenses of Insurance Committees. Mr. Groves also asked, on June 23rd, if the Minister of Health was aware that Local Insurance Committees had received notice of amended regulations which proposed to remove the necessity for the Minister to appoint a practitioner to serve on an Insurance Committee where there were only twenty-five members. Sir Kingsley Wood replied that there had been no change in the medical representation since 1922. The regulations referred to by Mr. Groves contained no new provisions. No evidence of dissatisfaction had reached him.

**Health Insurance Surpluses.**—On June 22nd Mr. Short asked the Minister of Health whether he had received representations from approved societies respecting the pooling of national health insurance surpluses. Mr. Neville Chamberlain said this subject had been dealt with in the evidence given by approved societies before the Royal Commission on National Health Insurance, and would receive his consideration when the Commission had made their report.

**Health Instruction.**—Asked whether he could take any steps to promote the medical education of the people, the Minister of Health said many local authorities already provided simple medical information, and a proposal to extend the powers of local authorities in this matter was now before Parliament. The

Ministry of Health had recently published a memorandum by the Chief Medical Officer on public education in health. Lord Eustace Percy (President of the Board of Education) said he did not think it necessary for him to suggest to local authorities and governing bodies that lessons in personal and public hygiene should form part of the curriculum at girls' secondary schools.

**Medical Referees.**—Asked about a letter to the press from a medical referee under the Workmen's Compensation Acts, the Home Secretary said medical referees were not civil servants but private practitioners paid by fees for their services. No rules had been laid down about communications by them to the press on subjects connected with the Acts, but he was sure the referees generally appreciated the responsibility of their special position. He saw no reason why the writer of the letter in question should not be retained on the list of medical referees. In answer to a further question the Home Secretary said he did not consider it necessary or desirable to limit the power of a medical referee to deciding the disability under which a man was suffering.

**Local Medical Research Laboratories.**—Mr. Graves, on June 23rd, asked if the Minister of Health had considered the handicap to local medical research committees in the non-provision of pathological laboratories in connexion with local hospitals; and whether, in connexion with the Government's plans of research work, he would consider the provision of such equipment for the use of local medical men. Sir Kingsley Wood, who replied, said that there were no funds available at present for the provision of pathological laboratories for the assistance of local committees of this kind. In any future developments of health policy the provision of such laboratories would be borne in mind.

**Milk and Disease.**—The Minister of Health has received representations from local authorities urging legislation to allow greater precautions to be taken against the spread of disease by milk. Asked whether he had introduced legislation making it compulsory for dairymen, cowkeepers, and milk vendors to give immediate notice to the local authority of any illness among their employees, Mr. Neville Chamberlain said the suggestion would be considered when the Milk and Dairies (Consolidation) Act, 1915, came into operation, and Milk and Dairies Orders had to be made under it.

**Mentally Defective Children.**—On June 22nd Lord Eustace Percy (President of the Board of Education) told Mr. Pelling that he was informed that the West Riding authority was making arrangements, in accordance with the suggestion contained in Circular 1319, for the supervision of all mentally defective children in the area whose admission to special schools could be secured. The matter was one which he had no doubt would be further dealt with in the programme of educational development which he had asked the authority to submit to him.

**Veneral Disease.**—On June 19th Mr. Neville Chamberlain, in reply to Sir J. Davidson, said that the joint deputation of the Society for the Prevention of Veneral Disease and the National Council for Combating Veneral Diseases which called upon him urged the necessity for immediate legislation to permit of the open sale of preventive material with concise directions for its use, as recommended by the Trevethin Committee. Since the deputation was received he had been in communication with the two societies on certain preliminary points which needed to be settled before the question of legislation could be considered, and he was awaiting a reply to a letter which he addressed to them on May 15th.

**Medical Services in Kenya.**—On June 22nd Lieut.-Colonel A. McDonnell asked the Secretary for the Colonies the percentage of local tax revenue expended on medical and sanitary services by the Governments of Kenya, Uganda, Tanganyika, Nigeria, Gold Coast, and Sierra Leone. Mr. Amery (Secretary for the Colonies) said that taking the figures from the current estimates, and including expenditure on sanitary services shown under other heads, the percentages were: Kenya, 12.3; Uganda, 20.8; Tanganyika, 17.2; Nigeria, 21.9; Gold Coast, 16.3; and Sierra Leone, 16.7. The Nigerian figures were, however, abnormal, owing to certain exceptional expenditure of a non-recurrent character.

**Mosquitoes in England.**—Mr. Neville Chamberlain said the prevalence of mosquitoes and of other noxious flies in many parts of the country had received expert study in the Ministry of Health for some years; the results were at the disposal of local authorities and of individual inquirers, and would be published shortly. It had been shown that the destruction of mosquitoes could not be secured by the adoption of any single or simple formula. Any useful action must depend upon the identification of the species prevalent in the area and the adoption of appropriate measures.

**R.A.M.C. Officers.**—On June 22nd Lieut.-Colonel Heneage asked the Secretary for War what was the shortage in Royal Army Medical Corps officers in the army; how many civilian doctors were employed instead; and what was the extra cost, if any, to the Exchequer. Captain King (Financial Secretary to the War Office) said the shortage of Royal Army Medical Corps officers was 86. Of these 30 would be under instruction at the Royal Army Medical College and elsewhere, leaving a shortage of 56 regular officers doing duty, which was made up by employing 21 non-regular officers and 35 civilian practitioners. No extra cost to the Exchequer was involved.

**Birth Control.**—On June 23rd Mr. Thurtle asked the Prime Minister if he could give the House an opportunity of directing that maternity centres provided at the cost of public funds should be free to give information on birth control to such married women as might desire it. Mr. Baldwin replied that in the present state of public business it would be impossible to find time for this, unless

an opportunity should arise on the Estimates of the Ministry of Health. Lady Astor asked whether the Labour party were not acutely divided on this question.

**Nurses' Hours and Pay.**—Colonel Day asked the Minister of Health a question as to the difficulty experienced by hospitals and infirmaries under his authority in obtaining the most suitable type of young women as nurses; whether he would make the necessary suggestion to local authorities, with a view to conditions, hours of labour, and remuneration being so improved as to allow nurses and sisters a greater measure of freedom for recreation, in order that the best type of women might be attracted to this vocation. Mr. Neville Chamberlain said he was aware that difficulties of this kind had been experienced, but he understood that the position was better, and that the conditions of employment had generally been substantially improved; he saw no advantage in intervention in the manner suggested.

**India.**—In reply to a question as to small-pox in Madras and Calcutta in recent years, and asking whether, seeing that small-pox in Indian towns had not been controlled by vaccination, the Secretary of State would require all the Governments of India to take steps to improve the sanitary conditions of the larger towns, Earl Winterton said that the Secretary for India was aware of the facts, but had no power to issue instructions as public health was a transferred subject. Mr. Dunning, on June 23rd, asked the Secretary for War whether the instructions in regard to vaccination, under which medical officers on duty with troops in India were required to satisfy themselves once in each year that every man, woman, and child under their care was sufficiently protected by vaccination, were still in force; and, if so, what explanation had the army medical authorities to make in regard to the cases of small-pox amongst British troops in India during 1920, 1921, and 1922, who were stated to have been vaccinated, or to have been vaccinated unsuccessfully, as recorded in the annual reports of the Public Health Commissioner with the Government of India for those years in question. Earl Winterton replied that the answer to the first part of the question was in the affirmative. The current regulations showed that the instructions applied only in regard to persons who consented to be vaccinated. As regarded the second part of the question, he had no detailed information supplied to the Public Health Commissioner by the army medical authorities. The average daily number of women employed in coal mines in British India in 1923 was 63,411, of whom 40,136 were employed underground. On June 22nd Earl Winterton stated that the amounts of opium consumed in Calcutta (including the suburbs, and the towns of Howrah and Bally) and at Rangoon in 1923-24 were respectively 185 lb. and 226 lb. per 10,000 of the population. The amounts consumed in the districts of Amritsar, Bombay, Karachi, and Madras were respectively 56, 86, 43, and 53 lb. per 10,000. No pronouncement by the medical profession in India as to the normal amount per 10,000 considered adequate was on record.

#### Notes in Brief.

The Departmental Committee which considered, among other matters, the suggestion that motor omnibuses and charabancs should be required to carry a first-aid outfit, was not satisfied that the circumstances warranted special regulations directing such provision.

The Foreign Office is not aware that any of the signatory Powers have deposited ratifications to the conventions and protocols drawn up at the Geneva opium conferences.

On January 1st, 1925, 1,205,267 persons in England and Wales were in receipt of Poor Law relief.

The Home Secretary is not aware that the metropolitan police refuse to allow the removal to hospital in private motor cars of persons injured in street accidents, but it is dangerous to move many common types of injury in any vehicle but an ambulance.

## Universities and Colleges.

### UNIVERSITY OF CAMBRIDGE.

The diploma in medical radiology and electrology has been granted to A. Burrows, M.D. Lond., E. P. Cumberbatch, M.B., B.Ch. Oxon., and G. H. Orton, M.D. Cantab. At a congregation held on June 20th the following medical degrees were conferred:

M.D.—E. V. Beale, R. H. White, F. D. Howitt.  
M.B., B.Ch.—T. S. Goodwin.  
M.B.—R. K. Wilson.

At a congregation held on June 23rd the following medical degrees were conferred:  
M.B., B.Ch.—T. H. Sims, M. D. Vint, F. N. Green, F. C. Cozens,  
F. A. H. Simmonds.  
B.Ch.—R. B. Fawkes.

### SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:  
Surgery.—C. E. Hagenbach, E. J. Jones, F. G. Martin, R. D. Mason,  
G. H. Weeber, J. W. Whitney.  
Medicine.—L. H. Mackay, C. J. Rozario, H. Winstanley, H. J. F. Wood,  
Forensic Medicine.—T. H. Harrison, E. W. D. Long, C. S. Netscher,  
J. I. N. O'Sullivan.  
Midwifery.—T. H. Harrison, A. H. Henson, N. H. Ibrahim.  
The diploma of the Society has been granted to Messrs. I. H. Mackay, C. J. Rozario, and H. Winstanley.

## The Services.

## INDIAN MEDICAL SERVICE.

## ANNUAL DINNER IN LONDON.

The annual dinner of the Indian Medical Service in London, which was held on June 17th under the chairmanship of Lieut.-Colonel A. W. Alcock, C.I.E., F.R.S., was conspicuously successful. It was attended by ninety-two officers and three guests. Among the guests was Lieut.-General Sir W. B. Leishman, K.C.B., K.C.M.G., F.R.S., Director-General of the Army Medical Service. This was an innovation, and so was the fact that the speeches after dinner, though not long, were a little more than formal votes of thanks. The Chairman, in proposing the toast of "The Service," sketched the scientific achievements in the past of members of the Indian Medical Service, and said that officers still on the active list were carrying on the tradition. The toast of "The Guests" was given by Sir R. Havelock Charles, G.C.V.O., K.C.S.I., who laid particular stress on the presence of the Director-General A.M.S. Sir William Leishman, on rising to reply, was warmly received; he also paid a tribute to the scientific work of officers of the Indian Medical Service, and went on to express the pleasure with which he found himself among them. Then Sir Leonard Rogers, C.I.E., F.R.S., proposed the health of the Chairman, and spoke of the high value of the scientific work done by Colonel Alcock both in India, and since his return home, as a member of the staff of the London School of Tropical Medicine. Colonel Alcock having replied, a toast to the two secretaries, Colonel John Anderson, C.I.E., and Colonel J. J. Pratt, was received with great enthusiasm. Coupled with their names was that of Lieut.-Colonel Fleming, the honorary secretary in India. Colonel Anderson, in the course of his reply, said that, largely through the exertions of Colonel Fleming, both the number of members subscribing to the dinner fund and its financial position had greatly improved. He went on to relate some stories, with which we regret we are unable to enliven our pages. Colonel Pratt also replied, and the company broke up to renew old friendships, some of those present not having met since they served together in India thirty or forty years ago. The following is a list of the members and guests present:

**Guests.**—Lieut.-General Sir W. B. Leishman, K.C.B., K.C.M.G., F.R.S., Sir Dawson Williams, C.B.E. (the *British Medical Journal*), Dr. E. C. Morland (the *Lancet*).  
**Members.**—**Major-Generals:** Sir R. H. Charles, G.C.V.O., K.C.S.I., Sir G. G. Giffard, K.C.I.E., C.S.I., G. F. A. Harris, C.S.I., R. Heard, C.I.E., Sir P. Heltz, K.C.I.E., C.B., O.M.G., C.S.I., A. Houston, C.I.E., J. B. Smith, C.B., C.M.G., C.S.I., D. Munro, C.B., C.M.G. **Colonels:** H. J. Crimmin, V.C., C.B., C.I.E., A. A. Gibb, J. A. Hamilton, C.M.G., A. J. Macnab, C.B., O.M.G., E. L. Perry, D.S.O., J. J. Pratt, H. Austen Smith, C.I.E., C. N. C. Wimberley, C.M.G. **Lieut.-Colonels:** W. G. P. Alpin, O.B.E., J. Anderson, C.I.E., R. F. Baird, G. T. Birdwood, E. W. C. Bradfield, O.B.E., J. T. Calvert, C.I.E., D. G. Crawford, J. M. Crawford, O.B.E., C. D. Dawes, G. L. Dunn, A. M. Fleming, A. T. Gage, C.I.E., E. V. Hngo, O.M.G., T. Hunter, C.I.E., G. H. James, C.I.E., S. P. James, J. G. Jordan, R. S. Kennedy, D.S.O., M.C., J. C. G. Leonard, R. McCarrison, C.I.E., F. O. N. Mell, C.I.E., W. H. T. R. Mulrooney, J. G. P. Murray, F. O'Keefe, C.I.E., C.V.O., N. Rainier, C. H. Reinhold, Sir J. R. Roberts, C.I.E., Sir L. Rogers, C.I.E., F.R.S., E. R. Rost, O.B.E., H. E. Stanger-Leathes, S. Browning Smith, C.M.G., R. Steen, Ashton Street, W. A. Sykes, D.S.O., C. E. Thompson, W. H. Thornhill, J. H. Tull Walsh, H. J. Wilson, O.B.E., H. G. L. Wortabet, A. C. Younan. **Majors:** H. L. Chambers, O.B.E., D. Coutts, M.B.E., G. F. Graham, A. E. Grisewood, R. Knowles, B. E. M. Newland, P. M. Rennie, C. J. Stocker, M.C. **Captains:** P. M. N. Antia, H. L. Barker, S. D. Billmore, Leo Blake, H. Horan Brown, H. R. Cursetji, W. P. Hogg, M.C., N. S. Jatar, D.S.O., V. R. Mirajkar, C. S. V. Ramanan, W. C. Spackman, P. Veyra.

## OFFICERS FOR THE R.A.M.C. SUPPLEMENTARY RESERVE.

In an official announcement issued on June 16th the War Office states that commissions in the Royal Army Medical Corps Supplementary Reserve of Officers are open to members of the medical profession engaged in civil practice. The object of this Reserve is to complete and maintain the various medical units of the Regular Army at war strength on mobilization; and the officers are divided into two categories. Those in the first category (Category B) have to undergo a preliminary training at the R.A.M.C. Depot, and an annual training of fourteen days with a selected formation or unit of the Regular Army. The preliminary training lasts normally for six weeks, but in the case of officers holding Certificate A or B of the Officers' Training Corps it is either dispensed with entirely or limited to three weeks. The other category (Category C) is intended for medical men with previous service and those possessing special professional qualifications. Officers in this cate-

gory are not required to do either preliminary or annual training. The present requirements include a number of specialists in surgery, medicine, mental diseases, x rays, pathology, bacteriology, and hygiene, who will as far as possible be employed in their special subjects on mobilization.

All commissioned officers are paid an annual gratuity of £25, and those in Category B, in addition, receive pay and allowances as for regular officers during all training. Normally an applicant's age should not exceed 32, but this limit may be dispensed with in special cases. The rank on appointment is that of Lieutenant. Promotion, in Category B, will be to captain after three and a half years' commissioned service; to major if qualified after twelve years' commissioned service, after which period officers will be transferred to the Regular Army Reserve of Officers; in Category C service, and after ten years' service transferred to the Regular Army Reserve of Officers. A candidate for Category C who served as an officer in the R.A.M.C. during the great war will be allowed to count such service for rank on appointment, for promotion to captain, and towards the ten years' period of service preceding transfer to the Regular Army Reserve of Officers.

Forms of application for appointment can be obtained, on written request, to the Under Secretary of State for War (A.M.D.I.), War Office, Whitehall, London, S.W.1.

## DEATHS IN THE SERVICES.

Colonel Matthew Denis Moriarty, Bengal Medical Service (ret.), died at Guildford on May 24th, aged 76. He was born on January 26th, 1849, the third son of the late Very Rev. Thomas Moriarty, M.A., D.D., Dean of Ardfert, and was educated at Trinity College, Dublin, where he had a brilliant career, gaining a medical scholarship on entrance as an undergraduate, and taking first place in the examination for the medical degrees, thereby gaining the university medical travelling prize. He graduated as B.A. in 1869, as M.B. in 1872, and subsequently proceeded M.D. in 1891, also taking the F.R.C.S.I. diploma in 1883. Entering the I.M.S. as assistant surgeon on October 1st, 1872, he reached the rank of colonel on October 25th, 1902, and retired on October 25th, 1905. Most of his service was passed in civil employment in the North-West (now the United) Provinces; on promotion to administrative rank he was appointed Inspector-General of Civil Hospitals in the Central Provinces. After his retirement he settled at Guildford, where he occupied himself chiefly in his favourite pursuit of gardening. In 1878 he married Janet Elizabeth, second daughter of the late Surgeon General James Irving, I.M.S. She died in India in 1887. He leaves two sons, the elder of whom is a member of the medical profession, and two daughters. Fleet Surgeon Edward Ferguson, R.N. (ret.), died at Merchiston, Edinburgh, on June 9th, aged 74. He took the L.R.C.S.I. in 1874, and the L.R.Q.C.P. in 1876; he entered the navy soon after, and obtained the rank of fleet surgeon in 1899. During the Chilian war, in 1879-83, he was serving on the Pacific station as surgeon of H.M.S. *Thetis*, and was landed to do duty in the Peruvian hospital at Lima; for this he received the thanks of the Government of Peru and its war medal.

The Territorial Army Ambulance Competition, Shield Competition, 1925, held at the Duke of York's Headquarters, Chelsea, on June 13th, was won by the 1st East Lancashire Field Ambulance with 367 marks out of a possible 400. The 125th (East Lancs) Field Ambulance was second with 354 marks.

## Obituary.

## PROFESSOR A. DEPAGE, Brussels.

We have to record with deep regret the death of Professor Depage of Brussels, after a long illness. He was well known throughout the surgical world, first as secretary-general of the International Society of Surgery, and afterwards as one of the most accomplished military surgeons produced by the war. Madame Depage, who spoke English well, was as well known in this country as her husband, and her tragic death in the foundering of the *Lusitania* caused widespread sorrow.

We are indebted to Sir D'Arcy Power for the following tribute to Professor Depage:

The death of Dr. Antoine Depage removes a great Belgian surgeon and deprives England of a staunch friend. My acquaintance with him dates from 1902, when he invented, organized, and, with the help of his brother-in-law, Dr. Lorthioir, carried to a triumphal issue the foundation of the Société Internationale de Chirurgie. He was the secretary-general whilst I acted as local secretary for Great Britain and Ireland. The meetings of the society were held triennially in Brussels until we became positively ashamed of the hospitality so lavishly bestowed upon us, and it was determined to meet where we could offer some return to our Belgian friends. The United States, Paris, and London received the society in turn, and at the

meeting in the United States Depage went as president; in that office he was succeeded by Dr. W. W. Keen, and he by Sir William Macewen. No sooner had he returned from the United States in 1914 than the war broke out, and he plunged at once into the career which made his name famous as a great military surgeon. In October, 1914, he opened Red Cross hospitals at Calais for the relief of the wounded, and a few months afterwards he established another at the Ocean Hotel at La Panne, where, with many English nurses, such good work was accomplished that it became the Belgian surgical headquarters. In all his labours he was most ably assisted by his devoted and fascinating wife. Perhaps one of the most trying events in my life was when I received a telegram at midnight saying, "Madame Depage drowned in the *Lusitania*. Find Depage in one of the hotels in the Strand and send him to Cork by the mail." A few weeks before she had spent the evening with us, confessing that she was going with a sinking heart to beg funds for the Belgian Red Cross, for she had never spoken on a platform. Her appeal proved satisfactory in the highest degree, and her devoted British friends afterwards subscribed generously towards a memorial for her. Working hand in hand, Dr. and Madame Depage were perhaps mainly responsible for the noticeable improvement in the standard of Belgian nursing which has taken place during the last thirty years. With this object in view Miss Cavell was invited in 1900 to leave England and take charge of his nursing home in Brussels. She accepted the invitation, worked splendidly, raised it to a high pitch of efficiency, and was in sole control from the beginning of the war until the civilized world was shocked to hear that she had been tried and shot as a spy by the Germans. A first-rate organizer, the great war found Depage already skilled in the work of a military hospital, for he had established a Belgian Red Cross hospital at Constantinople during the Balkan war. In Brussels his surgical clinic had long been conducted on the best modern lines. In 1920 his services to surgery were recognized by his election as a corresponding Fellow of the Académie de Médecine in Paris and by an honorary Fellowship of the Royal College of Surgeons of England, whilst his countrymen elected him to the distinguished position of president of the Faculty of Medicine in the University of Brussels, where he had long held the position of professor of pathology and clinical surgery.

#### THOMAS STEVENSON, M.D.Ed.,

LIEUT.-COLONEL R.A.M.C.T.(ret.),

Senior Surgeon, St. Paul's Eye Hospital, Liverpool.

THE death of Dr. Stevenson came as a great shock to his friends and colleagues, who thought he was in his usual good health and spirits. The end came suddenly on June 7th at Dyserth, where he was spending the week-end at his country house. Dr. Stevenson's career was devoted to ophthalmology, and for over thirty years he had practised the specialty with success. He studied medicine at the University of Edinburgh, graduated M.B., C.M. in 1886, and M.D. in 1912. He settled in private practice in Liverpool. His opportunity for becoming an ophthalmologist came when he obtained the appointment of assistant surgeon to St. Paul's Eye Hospital. There he came under the influence of the late Dr. George Walker, and by his assiduity laid the foundation of a sound knowledge of diseases of the eye, which established his reputation as an oculist. An ardent Volunteer, he early joined the local volunteer medical corps, and during the great war served as lieutenant-colonel with the medical forces in France. On his return he became the senior surgeon to the hospital, and was in active practice up to the end.

Dr. Thomas Stevenson was a man of engaging personality, a loyal colleague, and stanch friend. Considerate towards his patients, no trouble was too great, and he passed many hours in the service of the hospital. As an army medical officer no one could have been more thoughtful of his men. A memorial service was held on June 13th in the Lady Chapel of the Liverpool Cathedral. There was a representative gathering of his colleagues on the staff of St. Paul's Hospital and of many friends and patients to do honour

to the memory of one who had earned their esteem and affectionate regard. The tribute paid to him by the canon-in-residence was much appreciated by those present. It set forth the character of the man as he was known to all with whom he came in contact. Dr. Stevenson will be much missed by his colleagues, and not least for his affability and sincerity of purpose. He leaves a widow, with whom we desire to express our sympathy in the untimely loss of one who had endeared himself to so many.

We regret to record the death of Dr. JAMES CAMERON at the age of 55, after a long and painful illness. He received his medical education at Edinburgh, where he obtained the diplomas of L.R.C.P. and S.Ed. and L.R.F.P.S.Glas. in 1894. In 1895 he began practice at Loanhead, Midlothian, and married the daughter of Dr. Gilmour, for many years provost of Linlithgow. A colleague writes: Dr. Cameron was a genial, large-hearted personality, a staunch and loyal friend to his colleagues, and very popular with his patients. He had many activities outside his profession, being a keen and well known curler, a prominent Freemason in Midlothian and Edinburgh circles, and chairman of the local Unionist association. He took great interest in educational matters, being for many years a member of the parochial school board, and later a member of the education authority. He was a member of both the Midlothian and Edinburgh Panel Committees, and also of the County Insurance Committee. He was a chairman of the Lothians Division of the British Medical Association, and in recent years attended regularly the Annual Meetings of the Association. He was a major in the Territorial Division, R.A.M.C., and had a long connexion with the Lothian and Border Yeomanry. His vigorous presence and business capacity will be sadly missed by his colleagues. His two sons had died previously, one being killed in aerial warfare in France.

His many friends in Shropshire have seen with deep regret the announcement of Dr. JUSTIN McCALLUM MCCARTHY's death at Margate. Dr. McCarthy received his medical education at Aberdeen and Guy's Hospital; he obtained the diplomas M.R.C.S. and L.S.A. in 1876, and graduated M.D.Durham in 1898. A colleague writes: Dr. McCarthy commenced practice at St. George's, Shropshire, nearly fifty years ago, and for many years was one of the leading practitioners in the county. He was president of the Shropshire and Mid-Wales Branch of the British Medical Association for the year 1894-95, and president of the Midland Medical Society for the year 1907-08. He was a very sound and successful practitioner, beloved of his patients and most popular throughout the county; but it is for his public work, particularly in public health and education, that he will be mostly remembered. Dr. McCarthy entered the Salop County Council in 1892, and was elected chairman of the Public Health Committee in 1902, a post he held for twenty-one years. He devoted all the time that he could spare from a large and laborious practice to building up a real public health service for the county. His enthusiasm for "health" and his sympathy with the poor made this a labour of love. He was a justice of the peace for the county, and was made an alderman of the county council in 1906. In addition to many other posts that he held, he was chairman of the Shropshire Association for the Prevention of Consumption. When he retired from practice about twelve months ago on account of ill health, and left Shropshire to live in the South of England, his loss was felt very acutely throughout the whole county. Dr. McCarthy was a cousin of Justin McCarthy, the author and Irish leader. He leaves a widow, with whom much sympathy is felt.

We regret to announce the death of JOHN FERGUSON CARRUTHERS. He was the eldest son of Mr. Walter Carruthers of Inverness, and a grandson of Robert Carruthers, LL.D. At 14 years of age he won a scholarship at Fettes College, Edinburgh. He was successful both in work and in games, winning prizes in sport at Fettes

## Medical News.

and becoming a good cricketer. He received his medical education in Edinburgh, where he graduated M.B., C.M. in 1892. After an adventurous career in many parts of the world, Carruthers took the degree of M.D. with honours in Edinburgh in 1897. He practised for several years at Revelstoke in British Columbia, where he was medical officer of health. From 1903-05 he studied at Moorfields Eye Hospital, and then took up ophthalmic practice at St. Peter Port, Guernsey. Soon after the outbreak of the war he was appointed ophthalmic specialist at the Royal Herbert Hospital, Woolwich, where he remained until 1922. His duties in this post were extremely arduous, and it cannot be doubted that his unrelenting work undermined his health. In 1922 he was appointed ophthalmic specialist at Baghdad in the R.A.F. with the rank of squadron leader, but did not take up the post, and shortly afterwards retired. He married a daughter of Mr. W. Scott of Edinburgh, who survives him.

The death occurred on June 13th of a veteran practitioner, Dr. EDWIN J. SLADE-KING, who had reached the age of 95. He received his education at Edinburgh, London, and Paris, and graduated M.D. Edin. in 1853; he took the diplomas of M.R.C.S. Eng. in 1854, L.R.C.P. Lond. in 1858, and D.P.H.R.C.P. Edin. in 1876. He was a member of the council of the Royal Sanitary Institute, was president of the South-Western Branch of the British Medical Association in 1890, and a Fellow of the Society of Medical Officers of Health. For nearly sixty years Dr. Slade-King was advanced officer of health for Ilfracombe, but owing to his last, when he was one of the oldest, if not the oldest, medical officer of health in the country. For many years he was the county coroner. In December last he also resigned the office of medical officer of health under the Torrington and Dulverton Rural District Councils. Dr. Slade-King served for eighteen years on the Devon County Council, and when he decided not to seek re-election in 1922 he was co-opted a member of the Devon Education Committee.

The deaths are reported of the following well known foreign medical men: Dr. CLARO HOMER DE MELLO of Sao Paulo, the Brazilian statesman and psychiatrist; Dr. ALBERT REMY, the French ophthalmologist and inventor of the diploscope; Professor BATTISTA GRASSI of Rome, the malarialogist and one of the leading biologists of the day; and Professor GNOLAMO DAACOMO, a well known pharmacologist of Modena.

## Medico-Legal.

## DIAGNOSIS OF DISLOCATION.

SALTER AND SWIFT, JJ., sitting in the King's Bench Divisional Court on June 17th, allowed the appeal of Dr. Robert Leeming, medical officer to the Kendal Board of Guardians, from a judgement of Judge Chapman delivered at Great Grimsby County Court on February 18th, mulcting Dr. Leeming in £1,800 damages for negligence in failing to diagnose the dislocation of the left hip-joint of George Freeborn, formerly a travelling ganger, of Scunthorpe.

The hearing of the case in the county court was reported in the *BRITISH MEDICAL JOURNAL* of March 14th. Dr. Leeming pleaded (*inter alia*) the protection of the Public Authorities Protection Act, 1893, Section 1 (a), which provides:

"The action . . . shall not lie or be instituted unless it is commenced within six months next after the act, neglect, or default complained of, or in case of a continuance of injury or damage, within six months next after the ceasing thereof."

The plaintiff issued his writ on April 25th, 1924, six months and ten days after he left the defendant's care—that is, October 15th, 1923; but the county court judge held that no cause of action arose till damage occurred, that in this case damage occurred on November 1st, 1923, and that therefore the action was started within the six months.

Salter, J., in a judgement, in which Swift, J., concurred, said it might well be that by the time the cause of action accrued it was too late to sue, but the Legislature had deliberately passed this Act for the protection of public officials, even when they had been guilty of negligence. He could not agree with the county court judge that no damage accrued for several weeks after October 15th, 1923. He thought the damage began to accrue from the time when the doctor ought to have discovered the dislocation, which was some time before October 15th, 1923. Leave to appeal was given.

A MEETING of the Tuberculosis Society of Scotland will be held at the Scottish House of the British Medical Association, 6, Drumshough Gardens, Edinburgh, on Thursday, July 9th, at 4.30 p.m., when Professor Holger Moellgaard and Professor Knud Faber of Copenhagen will speak on the sanocrysin (gold) treatment of tuberculosis.

At the annual summer meeting of the Institution of Heating and Ventilating Engineers, held last week at Birmingham, Mr. Herbert G. Cuthbert read a paper on hot-water installations for large hospitals, founded on his experience with the Metropolitan Asylums Board. He stated that 2,800 to 3,000 tons of coal were consumed annually in many hospitals, for steam raising alone, besides 500 to 850 tons for other purposes. It was necessary, therefore, to give careful consideration to designing plants, which should be centralized. There should be ample capacity for storage of hot water, and spare or stand-by plant should be provided where a breakdown would cause the stoppage of a large part of the essential services. It was desirable to have suitable recording apparatus to furnish a record of the fluctuations in temperature and so as to have complete evidence of the running of the plant, and the shortcomings of the staff. He exhibited a number of graphs, taken from installations of the Metropolitan Asylums Board, showing the hourly consumption of hot water over the twenty-four hours of the day, both Sundays and week-days, which afforded interesting information as to where the hot water was used, and of the times and quantities drawn off.

THE Johnston-Lavis Geophysical Collection, bequeathed by the late Dr. Henry James Johnston-Lavis, student of University College, London, and afterwards in practice for some years in Naples, was formally opened by Sir Henry A. Miers, Vice-Chancellor of the University of Manchester, at a meeting in University College on Thursday last.

THE Fellowship of Medicine announces that on Friday, July 3rd, at 5.30 p.m., Sir John Thomson-Walker will give a lecture, open to all members of the medical profession, on urinary infections, in the West Lecture Hall of the Royal Society of Medicine. A four weeks' course in urology, beginning on June 29th, will be held at St. Peter's Hospital. The second week of the practitioners' course at the London Temperance Hospital begins on June 29th. The special courses to be given during July include one for a fortnight, starting on July 6th, in children's diseases, at the Queen's Hospital for Children, and a three weeks' course in neurology, at the West End Hospital for Nervous Diseases. A lot of night's course, beginning on August 4th, in general medicine surgery, and the special departments, will be given at the Prince of Wales's General Hospital. Starting on the same date, the All Saints' Hospital will give a month's course of instruction in urology. From August 24th to September 5th the Queen Mary's Hospital, Stratford, will hold an intensive course in medicine, surgery, and the special departments. Copies of the syllabuses and the programme of the Fellowship of Medicine may be obtained from the Secretary at 1, Wimpole Street, W.1.

THE annual general meeting of the West London Medical Chirurgical Society will be held at 5 o'clock on Friday, July 10th, at the West London Hospital, Innersmith, W.

THE fourth Annual Conference on Cremation, arranged by the Federation of Cremation Authorities, will be held in the Conference Hall, British Empire Exhibition, Wembley, at 3 p.m., on Wednesday, July 1st.

THE Council of Epsom College will shortly elect two girls to St. Anno's Home Scholarships of £48 n. year. Candidates must be fully 7 years of age and not over 12 and must be for not less than five years in independent practice in England or Wales. Application must be made on a form to be obtained from the Secretary, 49, Bedford Square, W.C.1, by July 7th.

THE eighteenth concert of Hospital-Trained Ex-Servicemen's Choirs will be held at the Chelsea Polytechnic, King's Road, S.W., on Saturday, July 4th, at 3 p.m.

An advanced course in otitis-inflammation will be held at the Toulouse Faculty of Medicine, under the direction of Dr. Escat, from July 6th to 13th. The course is open to French and foreign medical practitioners and students at a fee of 150 francs. Further information can be obtained from Dr. Vignier, Hospice de la Grave, Toulouse.

Dr. PERCY B. SPURGIN, who is honorary secretary of the Marylebone Division of the British Medical Association, has been appointed President of the Metropolitan Police Surgeons' Association for 1925-26.

THE second Imperial Entomological Conference, which began on June 9th, concluded its proceedings on June 18th, when the delegates of certain dominions, colonies, and dependencies who had attended it were entertained at dinner by the Government. The Secretary of State for the Colonies, who was in the chair, in proposing a toast, congratulated them on the success of the conference. He believed that the Governments of all nations, and not least the British Government, were beginning to realize the importance of such questions as the prevalence of diseases due to mosquitos, of trypanosomiasis, and of weevil in the cotton fields. He appealed to men of business in all parts of the British Empire to give attention to the matter and establish their own entomological staffs, but a comprehensive scheme of research and administration action was needed for the whole of the British Dominions. Mr. A. Gibson (Canada) praised the work of the Imperial Entomological Bureau.

Dr. G. E. BROOKER, chief health officer, Singapore, has been elected a life Fellow of the Royal Sanitary Institute. Dr. Robert Dick (Department of Public Health, Sydney, New South Wales), Dr. Duncan Forbes (M.O.H. Brighton), Dr. W. C. Laidlaw (Alberta, Canada), and Dr. E. C. Williams (County M.O.H. Glamorgan) have been elected Fellows.

A MONUMENT, consisting of a bas-relief by the sculptor Raoul Béraud, in honour of the 500 French doctors and medical students who lost their lives during the war, was unveiled on June 14th, at the Paris Faculty of Medicine, in the presence of the President of the French Republic, the Dean of the Faculty of Medicine, and a large and distinguished audience.

THE ninth congress of the Swiss Society of Dermatology will be held at Zürich on July 4th and 5th.

Dr. COSTANTINI has been nominated professor of clinical surgery, Dr. Lohlaue professor of anatomy, and Dr. Plucy professor of natural history and parasitology in the Algiers Faculty of Medicine.

A CONGRESS, convened by the International Council of Nurses, is to be held in Helsingfors, Finland, under the presidency of the Baroness Sophie Mannerheim, President of the International Council of Nurses, and matron of the Surgical Hospital, Helsingfors, commencing on July 20th.

MESSRS. J. and A. CHURCHILL announce for early publication *The Diabetic Life, Its Control by Diet and Insulin*, by Dr. R. Lawrence, Chemical Pathologist, King's College Hospital.

A VACATION course will be given at the Clinique Maritime, Coq-sur-Mer, Belgium, by Dr. Delcher, assisted by Drs. Wettendorf (Middelkerke) and Ledent (Lilège), from August 17th to 22nd. It will deal chiefly with the treatment of tuberculous disease of the bones and joints by surgical means, and by sea air and heliotherapy. The fee will be 100 francs, and full particulars can be obtained from Dr. Delcher, 38, Rue Stévia, Brussels.

THE seventeenth congress of the Italian Phreniatric Society will be held at Trieste, under the presidency of Dr. G. Pastorich, from September 24th to 27th, when the following papers will be read: Constitution in psychiatry, by Drs. M. Kobliasky and G. Vidoni of Genoa; psychiatry and psychoanalysis, by Dr. E. Weiss of Trieste; treatment of general paralysis, by Drs. N. de Paoli and Moadini of Ancona.

THE sixth congress of the Far Eastern Association of Tropical Medicine will be held at Tokyo from October 18th to November 7th. October 18th to 25th will be devoted to scientific meetings, and the 26th to sight-seeing in Tokyo. On the 27th there will be an excursion to Kamakura, from the 28th to November 1st to Nikko, Hakone, and Kyoto, and from the 1st to the 7th to Nara and Osaka. Further information can be obtained from the general secretary, Dr. O. Beggelen, Wettevreden.

THE second German Congress of Orthopaedics will be held at Hanover, under the presidency of Dr. Bade of Hanover, from September 14th to 16th, and will be followed by a visit to the watering places on the North Sea. The chief subjects for discussion at the congress are: development of bone, by Dr. Stoffel of Mannheim; disturbances in growth, by Dr. Munk Jensen of Leyden; and the physiology of bone, by Dr. Müller of Munich.

A POST-GRADUATE course will be held in Berlin, with the active participation of the Faculty of Medicine, next October. It will include lectures and demonstrations on general medicine, and a special course for ophthalmologists. Full particulars can be obtained on application to the Office of the International Post-Graduate Courses, Luisenplatz 2-4, Berlin, N.W.6.

A COMMITTEE has been formed to erect a monument to commemorate the late Professor Paul Delbet. Subscriptions should be sent to M. Prunet, 104, Avenue Ledru-Rollin, M. Thomas, 44, Rue Boileau, or M. Bellaager, 2, Rue Pigalle, Paris.

PROFESSOR SABRAZÉS has succeeded the late Professor Bergonié as director of the regional centre of Bordeaux and the south-west of France for combating cancer.

Dr. C. M. CORTEZO of Madrid has been nominated President of the State Council of Spain. This is the first time that this post has been held by a medical man.

DURING the International exhibition at Grenoble in October a medical congress will be held. Dr. Dupuy de Frenelle of Paris has been nominated president of the section of medicine; Dr. Delort of Paris, president of the section of gastro-enterology; and Dr. Roux-Dolmal, president of the section of French and foreign medical journals.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 15, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

## QUERIES AND ANSWERS.

### LARIAL AND CERVICAL WARTS.

Dr. MANASSEN (Friends' Hospital, Brummann, Beyrouth, Syria) asks for advice on the small cauliflower growths, very much like ordinary warts, dotted all over the inner and outer sides of labia minor and majora. The woman is about 60 years of age; the blood gave a negative Wassermann reaction. There is no history of gonorrhoea. The cervix presents one or two of these small warty growths, but is otherwise normal in appearance. He has in turn applied strong nitric acid, acetic acid, thermo-cautery, silver nitrate, carbolic acid, scraping the surface before cauterizing, antiseptic douches, etc., but has not obtained a permanent cure.

### STREPTOCOCCAL INFECTION OF TONGUE.

"PERPLEXED" has a patient who for six months has suffered from chronic streptococcal infection of the tongue, which is furred, dry, and fissured. He asks for advice in treatment. The teeth have been x-rayed and any doubtful ones removed. Other sources of local reinforcement for the infection have been excluded. Autogenous vaccines, mouth-washes, and antiseptic lozenges have been persevered with. Great attention has been paid to the general health and special care has been taken to avoid any irritating article of diet.

### INCOME TAX.

#### Replacement of Car and Change of Practice.

"V. F." made a claim in respect of the cost of replacing his car and "received one-third of the rebate this year." He has now left that practice and is told that he must lose the remaining two-thirds of the rebate allowed him.

The cost of replacing a car is deductible as a professional expense—that is, it falls to be treated in the same way as, for instance, the payment of a locum tenens. The result is to reduce the profits of the year in which the expense is incurred. Where the practitioner remains in the same practice during the three following years he receives a full allowance, spread out, so to speak, over that period. If, however, he leaves the practice, the benefit of the deduction accrues to the practitioner who takes it over, for that part of the three years which is still affected by the profits of the year which were reduced by the deduction. The result is perhaps not equitable as between the vendor of a practice and the purchaser, but is only more marked in degree than normally happens in connexion with other fluctuating

receipts and expenses whenever a business or practice changes hands. It is a consequence of the principle that the three years' average adheres to the business or practice, and not to the earnings of the individual.

## LETTERS, NOTES, ETC.

## A LONG SOJOURN.

Mr. V. P. NORMAN, F.R.C.S. (Bradford), writes: The following case of foreign body in the rectum is of some interest on account of the long time (seven months) before it was expelled, and the absence of any discomfort for several months. A married woman, aged 33, was operated on for a uterine fibroid in October, 1924. She was discharged from hospital on November 1st perfectly well, and remained so until last March, when she began to have increasing constipation and a sensation of fullness in the rectum. The constipation increased until, on May 19th, her bowels ceased to act, in spite of large doses of castor oil and Epsom salts. Feeling something protruding from the anus, she grasped it with her fingers and with difficulty removed a sodden inspissated piece of gauze, 8 in. long, 4 in. wide, and about 1 in. thick.

## SPUTUM EXAMINATION BY THE COLOUR BLIND.

Dr. E. W. BOWELL (South Norwood) writes: Dr. Constance Steelo (BRITISH MEDICAL JOURNAL, June 6th, p. 1064) recommends a special method of staining sputum slides in order to make the tubercle bacilli evident to a colour-blind observer. This may, however, be managed more simply if the slide is stained in the ordinary way and examined with a suitable colour screen. The Wratten No. 45 shows (to a normal observer) the fuchsin-stained organisms of a deep black colour, while the prominence of the other (blue-stained) structures is diminished. The colour-blind observer will probably see exactly the same. The colour screen may be obtained enclosed between circular glasses of a size which will fit the substage diaphragm carrier. To try the effect a piece of the coloured gelatine (to be obtained for a few pence) will serve quite well. No glass screen that I have tried has so good an effect; the reason for this is evident when the glass and the coloured gelatine are examined with a hand spectroscopic. I refrain from further details, as the No. 45 screen is easily obtainable and answers the purpose.

## MULTIPLE INFECTION BY TAENIA.

Dr. W. FIFFE DOWARD (St. Luke's Hospital, Haffa) writes: On January 6th, 1925, a Bedouin, aged 40, attended the outpatient department complaining of epigastric pains and constipation. He stated that he had had slight intermittent pains in the stomach for several years, always worst during the night, but only recently had they become severe. For several weeks the pain had recurred frequently, and, when severe, spread upwards into the chest. He had occasional attacks of heartburn, and on several days previously had induced vomiting to relieve it. The bowels were opened with difficulty every second day. The patient was a sparely built man, 5 ft. 6 in. in height, and weighed (clothed) 8 st. 2 lb. He was very thin and slightly jaundiced. The tongue, large and flabby, was indented and coated with yellow fur. The spleen was much enlarged (2½ fingerbreadths below the costal margin) and the liver slightly (1 fingerbreadth below the normal lower level). Peristalsis was very active and readily seen through the thin abdominal walls. Palpation revealed indistinct soft masses, evidently faecal accumulations. Further questioning secured the information (withheld previously as too common to mention) that he had had chronic malaria for years, and had frequently observed tapeworm in his stools. He was admitted that day and treated with ext. filicis liq. next day. The worm passed looked unusually large, and on careful search sixteen heads of *Taenia mediocanellata* were found. Unfortunately the total length of worms passed was not measured, as the patient refused to swallow the medicine. The following day the patient was much improved, and was so completely free from pain, that he refused to stay longer in hospital, so that it was impossible to observe whether the gastro-intestinal symptoms were permanently relieved or not.

## SLEEPLESSNESS.

"F. G. G." writes to express the view that many cases of insomnia at and after middle age are due to the increased blood pressure associated with advancing years, and states that he has frequently found a dose of calomel (2-3 grains), followed by a saline aperient next morning before breakfast, to bring about a cessation of the trouble, at any rate for a time, by reducing blood pressure. The dose can be repeated—if and when required. I never, he adds, think of hypnotic drugs in these cases.

LIEUT.-COLONEL E. O. C. MAUNSELL, I.M.S. (ret.) (Ealing), writes: Lieut.-Colonel Reinhold, I.M.S. (June 6th, p. 1064), refers to the same time in a coffee-growing district in India, and among the planters and their wives I found some, like myself, who were unable to drink coffee at night, black or otherwise, on account of a certain amount of insomnia produced. There no question of adulteration arose; it was the berry, and nothing more than the berry.

## OVERCLOTHING OF CHILDREN.

Dr. MARION E. MACKENZIE (Leeds) writes: With regard to the influence of clothing on health, I was interested to find, in judging a "health competition" for children recently, the marked effect of overclothing, apparently resulting in poorly developed chests and very feeble breathing. Where the chests were badly developed but the clothing light, it seemed to me that the breathing was not nearly so feeble. According to Sir Robert Philip's teaching, poor expansion with feeble breathing is a very serious matter in predisposing to phthisis, and therefore it is important that school children should not be overclothed. Most of the girls examined wore "Liberty bodices," originally designed to give greater freedom by serving the place of braces and discarding the voluminous skirts. These, however, in most girls, except some of the babies and toddlers (who, by the way, were much more sensibly dressed), were still used, the "Liberty" bodice being only an added encumbrance. Most of the children had splendidly developed legs but poorly developed chests. I was particularly struck with one beautiful child till I saw her chest: her teeth excellent, legs perfectly moulded and firm, but her breathing was so feeble I had to disqualify her. She had seven layers of clothes! The good development of the legs I put down to their freedom from clothes; all the children wore socks, not long stockings. What has been proved good in the sunlight treatment of tuberculosis should surely be good in its prevention, and with all due deference to Dr. Poynton (JOURNAL, June 6th, p. 1059) I can hardly support his view that because some girls get cynosed legs all girls should be "stuffy old Victorians," any more than it is reasonable to doubt the healthfulness of cold bath because some people cannot stand it. But I understand he does not expect us to be reasonable. "I can give you an argument, but I cannot give you an understanding," he says in effect! May I dare to criticize men's clothing, especially on a hot June day? Is it reasonable? Might not medical men reform it if only for the sake of the discomfort it gives us to look at them in this weather?

## SYNCHYSIS SCINTILLANS.

Dr. J. BARKER SMITH, L.R.C.P. (Louden, S.E.), writes: As I am able to watch the cholesterol particles in my eyes experiencing the degeneration of the vitreous humour associated with the above condition, I think I am able to confirm the fact of cholesterol taking on other properties when exposed to forms of light; also to contribute a link with respect to the equivalent of stimulation acting upon cholesterol particles. In a short letter which appeared in the BRITISH MEDICAL JOURNAL, April 5th, 1924 (p. 652), dealing with this subject of scintillating particles (cholesterol) in the eyes, I described two movements—one, movements in the lymph, floating movements; the other, darting movements—the latter determined by certain stimulants, notably ten, also by exercises in the open sunlight, and by a rod of nrc carbon held in the hand. The effects of the nrc carbon on my electric incanescences were also determined by a galvanometer run by from electric installations, before and whilst holding such rod of nrc carbon. I would suggest, then, that what I am witnessing in the eye is taking place throughout my whole body, and that the luminous particles which Mr. C. H. Collings described, and which ultramicroscopists have found in all vegetable and animal cells, may be cholesterol, and that cholesterol, with its high percentage of carbon (more than 80 per cent.), may act as the rod of nrc carbon in our economy. I mean by equivalents of stimulation, such as you have discussed in your leading article May 30th, 1925, with respect to antirachitic factors.

## MEDICAL GOLF.

A MATCH was held at Moor Park Club, Rickmansworth, on June 2nd, between the Medical Golfing Society "A" team and the British Dental Association Golfing Society "A" team. The match was keenly contested and ended in favour of the Dental Golfing Society, who won by 10½ points to 9½. The outstanding feature of the match was the morning round played by Mr. H. E. Warren Williams against Dr. H. A. Watney. Mr. Warren Williams went round in 73 (38 out and 35 home), the bogey for the course being 78.

THE summer meeting of the Shropshire Medical Golf Association was held on the Church Stretton links on June 7th. The following are the results:

*Captain's Prize* (presented by Dr. George Higginson, Church Stretton), *eighteen holes medal play*.—Dr. Beckett, 87-13=74; Dr. Urwick, 90-15=75; Dr. Richardson, 89-12=77; Dr. Crofton, 93-16=77; Dr. Ireland, 88-10=78; Mr. Bradford, 91-13=78; Dr. Elliott, 88-9=79; Dr. Lawrence, 91-12=79.

*Foursomes v. Bogey*.—Drs. Hayden and Clarke=1 down. Drs. Anderson and Urwick=2 down. Drs. Higginson and Elliott=4 down. (Twenty-six entries.)

## VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 225.

#### 1. Diagnosis of Meningitis by Fluorescein.

O. JERVELL (*Acta Med. Scand.*, Supplement VII, 1924, p. 115) describes a test which depends on the fact that the permeability of the meninges is increased when they are inflamed. There are, in fact, several substances which pass from the blood through the meninges into the cerebro-spinal fluid only under abnormal conditions. The substance which the author has tested in a hospital in Christiania is uranin, or sodium fluorescein, the fluorescence of which does not disappear in a solution till diluted to 1 in 10,000,000. The procedure adopted was to give 2 grams by the mouth, or by the intramuscular injection of a 20 per cent. solution when the patients were unconscious. Three hours later lumbar puncture was performed, and if the cerebro-spinal fluid was cloudy it was centrifugalized. By adding water to the cerebro-spinal fluid till fluorescence disappeared the amount of uranin in the cerebro-spinal fluid could be estimated. Of the 74 patients thus examined, 18 were suffering from various forms of meningitis. In 8 of the 56 cases representing diseases other than meningitis there was no fluorescence, although there was a dirty green colour. In 10 other cases belonging to this group the cerebro-spinal fluid was faintly fluorescent. In the remaining 38 non-meningitis cases the cerebro-spinal fluid was perfectly clear. In all the 18 cases of meningitis fluorescence was demonstrable, and with the exception of three cases this fluorescence was intense. The author claims that the test described is a simple and rapid means of distinguishing between meningitis and other diseases which may simulate it clinically. The test does not, however, distinguish between the different forms of meningitis.

#### 2. Spontaneous Immunization to Diphtheria.

P. LEREBoullet and P. JOANNON (*Paris méd.*, October 25th, 1924, p. 325) state that the acquiring of spontaneous immunity to the Klebs-Loeffler bacillus without a previous attack of clinical diphtheria has long been recognized. The earlier writers such as Tronssenc and Peter had discovered this by clinical observation and the negative results of attempts at inoculation. The present authors, as the result of observations on 113 children in a surgical pavilion at the Hôpital des Enfants Malades in Paris, found a relatively low percentage with positive Schick reactions—namely, 22 per cent. Another unexpected result was that there were more negative reactions among children aged from 2 to 5 than among those aged from 5 to 6. Most of the cases with a negative Schick reaction were to be found among children who had been in hospital for the longest period, and not among the oldest patients. There was not a single positive reaction obtained among children who had been in hospital for more than a year. In no instance was a negative reaction replaced by a positive one, but, on the contrary, three out of sixteen children with a positive reaction subsequently became negative. The six cases of clinical diphtheria which occurred in the pavilion in the course of seven years were found among children whose stay in the hospital had been relatively short—namely, one to four months. Immunization does not always take place in a latent manner, but is sometimes preceded by a slight and transient indisposition, associated with febricula, dysphagia, and redness of the throat with or without specks of deposit, all the symptoms subsiding in a few days without a bacteriological examination being made. The authors think, therefore, that an attenuated attack of diphtheria is one of the factors producing immunity to the disease.

#### 3. Insulin and Diabetes Mellitus.

P. J. CAMMIDGE (*Journ. Amer. Med. Assoc.*, November 1st, 1924, p. 1423) regards diabetes as a symptom-complex originating in a variety of ways, and eventually causing a progressive deficiency of the internal pancreatic secretions if the primary cause is not removed or controlled. Although the pancreas plays an important part in its pathology, it is held that the disease is not of constant etiology or pathology; it is not invariably due to a pancreatitis, but may arise from other causes. Probably disease of the pancreas, with absolute deficiency of its internal secretion, is the essential cause of the rapidly developing form of diabetes most common in young people. In the more slowly developing diabetes of later years, in which an intermittent glycosuria becomes persistent, with the gradual development of metabolic disturbances, absolute deficiency of the internal secretion is

secondary, and occurs in the later stages either as a result of continued relative deficiency, or as a consequence of slowly progressing interlobular sclerosis. Cammidge adds that the exact etiology in each case must be determined; in many instances in which insulin would otherwise have been indefinitely continued the discovery and successful treatment of the primary cause of the carbohydrate metabolic defects enabled it to be discontinued, or avoided altogether.

#### 4. Multiple Whitlows in Epidemic Encephalitis.

O. SCHIRMER (*Schweiz. med. Woch.*, October 23rd, 1924, p. 984) records a case of epidemic encephalitis in a man, aged 33, complicated by multiple whitlows, which involved first the fifth, fourth, and third fingers successively of the left hand, in which the tremors and motor deficiency were most pronounced, and then the fifth and fourth fingers of the right hand. The condition was probably due to a trophic change like that present in syringomyelia and Morvan's disease; but while in these two disorders anaesthesia is sufficient to explain the condition, in the present case there was no sensory disturbance, nor was there any vasomotor change. The rapid recovery, in spite of the considerable loss of tissue, was in favour of a trophic origin, as a purely exogenous infection would not have cleared up in so short a time and almost without reaction. The situation of the nervous lesion was probably the cerebral centre of the hypothetical trophic nerve fibres and not the peripheral nerves.

#### 5. Pituitary Deficiency.

J. PERKINS (*Boston Med. and Surg. Journ.*, November 20th, 1924, p. 973) has made a clinical study of 31 cases of deficient functioning of the anterior part of the pituitary in women. He calls attention to the changes which occur in the skin, the tendencies to sterility or miscarriage, the menstrual and visual disturbances, headaches, and dreams. In all the cases dilated blood vessels were present on the thighs, and nearly all the patients had irregular deposits of fat, pendulous breasts, tendency to bruising and free perspiration, terror dreams, and headaches. Only by following up histories over a long period could the primary cause be discovered, since the symptoms primarily due to endocrine dysfunctioning were often the same as those produced by other causes. Visual disturbances, unrelieved by glasses, were relieved by administering the gland extract, as also were the symptoms of dizziness and staggering gait. Perkins adds that cases presenting some or all of the above features suggest the existence of a symptom-complex caused by anterior pituitary deficiency for which treatment by anterior pituitary extract is indicated, since in the cases recorded improvement followed its administration.

### 

#### 6. Operative Treatment of Chronic Ascites.

F. PARKES WEBER (*International Clinics*, vol. 1, Series 34, p. 87) urges the value of treating selected cases of chronic ascites by omentopexy, and maintains that the unpopularity of the Talma-Morison operation is traceable to the fact that its good results are often considerably delayed. He remarks that the diagnosis of the cause of chronic ascites is sometimes difficult: hepatic disease may be syphilitic and not alcoholic; tuberculous or cancerous conditions have also to be considered in this respect. The author argues that the part played by alcohol in hepatic cirrhosis has been exaggerated, but that it is probable that alcohol lessens the resistance of the hepatic cells to microbic infections and to toxins derived from the alimentary canal. He adds that the cirrhosis in many cases represents a reactionary or regenerative process, and describes two processes in typical cases of nodular cirrhosis: (1) attacks of acute parenchymatous necrosis; and (2) intestinal fibrosis, with nodular regenerative growth of gland tissue. He believes that a certain amount of chronic localized peritonitis is often present in hepatic cirrhosis, favouring the development of peritoneal adhesions and new vascular channels, as does a successful Talma-Morison operation. He adds that the collateral venous circulation in hepatic cirrhosis is by the oesophageal veins, and that a successful omentopexy operation should assist nature, the formation of veins in the artificially produced omental adhesions removing the necessity for excessive dilatation of oesophageal veins, which might later on cause fatal haematemesis. He gives detailed accounts of several

cases which he has observed, and concludes that usually repeated paracentesis will be required after the operation of omentopexy, even though the final result of the operation is good.

#### 7. Fractures of the Shaft of the Femur.

W. C. CAMPBELL and J. S. SPEED (*Surg., Gynecol. and Obstet.*, November, 1924, p. 642) find that the results of treatment of fractured femur are far from satisfactory in many cases. They consider that the two best methods of treatment are gradual reduction by suspension and traction with the Balkan frame, and immediate reduction and plaster fixation. When properly used the plaster cast is considered the most reliable method of fixation; the authors have used it in 153 cases of fracture of the shaft of the femur. A plaster cast can, they think, be put on with safety at once. The greatest objection to its use is that the ankle and knee joints are immobilized for a long period. In children the resulting stiffness clears up in a few days; in adults the fixation may cause permanent limitation of motion, but satisfactory reduction and union should not be endangered on this account. This treatment of fractures in children gives excellent results, and young growing bones can correct even a marked deformity. They add that in adults better results are probably obtained by the plaster cast than by any other method; non-union in these cases is due chiefly to malposition.

#### 8. The Urochromogen Reaction in Surgical Tuberculosis.

M. GELDMACHER (*Deut. Zeit. f. Chir.*, October, 1924, 5 bis, 6 Hft, p. 399) has employed Weiss's urochromogen reaction in 50 cases of surgical tuberculosis at the Cologne University surgical clinic during the last fifteen months, and has come to the conclusion that it is only of value when the observations of the reaction are continued over a long period. When employed in association with other prognostic methods the test gives some indication as to the powers of systemic resistance, and is therefore of undoubted prognostic value. If the reaction is constantly positive it shows that the disease is of considerable severity, and it is a warning sign, even in cases where the tuberculous process is apparently not progressive. It is possible, however, that the reaction may become negative and the patient may improve even after it has been positive for six months. The disease may be regarded as completely cured when urochromogen can no longer be found in the urine. With a persistently negative reaction, bone and joint tuberculosis should be treated by conservative methods, including minor operations, such as sequestrectomy, which do not interfere with the function of the limb involved. A radical operation in such cases is a blunder. Even with a persistently positive reaction, amputation and disarticulation are only indicated when the other prognostic signs point to an unfavourable issue. In amyloid disease of the kidneys urochromogen is not excreted, which indicates extreme renal insufficiency, and is therefore a very unfavourable sign. Goldmacher recommends that Weiss's test should be used in out-patient practice as well as in patients confined to bed.

#### 9. Urethrolithiasis.

C. C. MAPES (*Urol. and Cut. Rev.*, September, 1924, p. 517) employs this term to denote the presence of a calculus within the urethra irrespective of its original site. In accordance with the nomenclature proposed by Suter the calculus may be described as antechthonous, heterochthonous, or amphichthonous, according as it is formed within the urethra, formed wholly outside it, or originates outside the urethra but increases in volume by deposition of new layers after reaching the urethral lumen. Urethroliths may be massive or diminutive, simple or multiple. In about one-third of the cases on record multiple calculi were found. Karajew removed 85 from a sac proximal to the prostate, and 415 more were removed from the urethra. The commonest types being lozenge-shaped, one flat surface of the individual discs articulating with each other. In 405 cases collected by English the calculi were found impacted in the urethral lumen or in associated diverticula. Five of the patients were under 1 year, twenty-three under 2 years, ninety-two under 10, thirty-five between 10 and 15, twenty-two between 16 and 20, forty-one between 20 and 30, and thirty-nine between 30 and 40, while in the rest the age was not stated. The anatomical sites were: membranous urethra 42 per cent., penile urethra 58 per cent., of which the pendulous portion, 13.7 per cent. were scrotal, and may be acute or chronic; they usually depend to a greater or less extent upon (a) the size, location, and conformation of the urethroliths, (b) primary or secondary formation, (c) the presence or absence of urethral stenosis, (d) whether or not infection has supervened. In infants and young children

there is evidence of intense urethralgia, urethral spasm, and dysuria, with more or less dribbling of urine, and unless the condition is relieved, urethral rupture, extravasation of urine, and death may ensue. In adults there is an acute type in which the urethral lumen becomes suddenly obstructed, and a chronic type in which more or less uro-genital disturbances have been previously noted in the form of attacks of pyuria and haematuria, urethral spasm, and uroecytic irritation. Urethroliths distal to the prostatic portion are easily detected by external palpation, but the diagnosis should be confirmed by urethroscopy, cystoscopy, and x-ray examination. Treatment is exclusively surgical. Meatotomy should be performed as a preliminary measure, followed by lithotomy or litholapaxy, except in complicated cases, or when the urethrolith is lodging in the prostatic or membranous portion, when external urethrotomy is indicated.

## Therapeutics.

#### 10. Intravenous Injection of Antirabic Vaccine.

J. MORISON (*Indian Journ. Med. Research*, October, 1924, p. 333) has treated persons severely bitten by animals proved to be rabid, or whose behaviour suggested rabies, by intravenous injections of antirabic vaccine. At first one dose of 2 to 3 c.cm. was given at the end of the usual fourteen days' treatment. Later the course of treatment was begun with one, still later with three, intravenous injections. After 59 cases had been treated, with three failures, the number of doses was increased to five. Fifty-nine more cases were treated with five doses before a failure occurred, when the course was increased to seven. Up to date 96 cases have been treated with five to seven doses intravenously, with one death. The vaccine is the ordinary 1 per cent. brain and cord emulsion of carbolized fixed virus. The rate of injection should not exceed 0.5 c.cm. a minute, and the dose is 2 c.cm. The patient may complain of tingling in the hands and feet as well as headache during injection of the first 0.5 c.cm., but the symptoms pass off before 1 c.cm. has been administered. No local or general symptoms have followed intravenous injection, which is preferred by many patients to the subcutaneous method. It is too early to estimate the value of the method, but as 720 intravenous injections have been given to 169 persons without a single accident or any alarming symptoms, the treatment may, according to Morison, be regarded as safe.

#### 11. Treatment of Varicose Ulcers.

L. DE GAETANO (*Rif. Med.*, October 27th, 1924, p. 1009) speaks very favourably of the following method of treating chronic varicose ulcers. Cleansing and disinfection of the skin is obtained by the use of rectified benzine and acidified alcohol (acetic acid 20 m., alcohol 100), and a suitable anti-eczema ointment is applied. This preliminary preparation lasts three to ten days. The leg is then elevated and a layer of sterilized gauze placed over the ulcers; strips of diachylon plaster are applied from the toes up to the knee, and a firm bandage fixed over all. This is left on for eight days; when it is removed there is usually a free collection of pus, but beneath it healthy granulations appear. The author suggests that in the process of skin maceration which goes on under the dressing absorption of auto-vaccines takes place. Patients are encouraged to walk about whilst under this treatment, and the results are said to be better than with rest in bed and immobilization of the limb.

#### 12. Vaccination against Whooping-cough.

A. H. MEYER, M. KRISTENSEN, and E. SÖRENSEN (*Acta Paediatrica*, October 25th, 1924, p. 21) review the literature and record the results obtained with a vaccine containing 10,000 million Bordet-Gengou bacilli per cubic centimetre. The cases were divided into three groups. The first group consisted of 198 hospital cases in which the vaccine was used as a prophylactic. Twenty-two children contracted whooping-cough, but in nearly all these cases the attack was slight or developed before the vaccination had been completed. The authors are of opinion that the vaccine was of prophylactic value, although means of control were lacking. The second group consisted of 127 cases in children's homes, where 37 contracted the disease. In this group also the results confirmed the prophylactic value of the vaccine, but there was also a lack of control cases. The third group consisted of cases reported by general practitioners, especially in the Faroe Islands, who had used the vaccine both in prophylaxis and treatment. All the Faroe Island practitioners reported that the vaccine, which they had used at 2,100 cases, as the vaccinated less severely than the unvaccinated. The opinions were divided as to its prophylactic value. The

vaccine was given subcutaneously three times, with four days' interval between each injection, the first dose consisting of 0.5 c.cm., the second of 0.7 c.cm., and the third of 1 c.cm. Smaller doses were used in some very young patients. At the Blegdams Hospital intramuscular injections were given daily in doses of 0.1, 0.2, 0.4, 0.8, and 1 c.cm. on five successive days.

### 13. Treatment of Diabetes Mellitus with Protein Substances.

G. SINGER (*Klin. Woch.*, October 28th, 1924, p. 1935) records his experience of treating diabetes mellitus with intramuscular injections of proteins. Caseosan was the protein usually employed. The injections were given twice daily, half an hour or an hour before the chief meals, every day, or every two days. Very small doses of caseosan were injected at first (1/2 c.cm.); and only gradually the dose was increased to 5, 8, or 10 c.cm. From his observations the author concludes that in cases of diabetes of medium severity, and also in severe cases, by the continued administration of non-irritating protein substances, together with dietetic restrictions, the excretion of sugar and ketones can be checked, or at least the glycosuria can be considerably reduced. In successful cases, after the rapid cessation of glycosuria and the diminution of blood sugar, a gradual increase of the carbohydrate tolerance was obtained; and the protein injections seemed to aid in increasing the tolerance. Singer found also, in less successful cases, that better results could be obtained by the combination of protein injections with a restricted diet than by diet restriction alone. The author draws attention especially to the rapid healing of many complications under the protein treatment. Strikingly good results are claimed in diabetic gangrene and cellulitis. Particularly noteworthy was the permanence of the good effect of the protein injections after the treatment had been discontinued. The good effect continued for many weeks.

## Radiology and Electrology.

### 14. Actino-therapy in Children's Diseases.

P. FONTYNE (*Le Scalpel*, November 1st, 1924, p. 1153) reports the results of a year's treatment of a number of children with a 1,000 candle-power quartz and mercury-vapour lamp. He concludes that ultra-violet rays have (1) a specific curative action in infantile tetany, rickets, and craniotabes, and (2) a beneficial general action on children's nutrition. One of his four cases of infantile tetany was a boy, aged 8 months, who had had frequent and alarming convulsions for five and a half months after admission to hospital, in spite of medicinal treatment. This was discontinued when the light treatment was started, and the child was cured completely in fifteen days. In spite of the fact that two of the other three patients returned to deplorable home conditions, they all did well. Two of these children had lost a brother or sister recently from convulsions. Fontyne's other patients made rapid recoveries, and he concludes that the treatment is absolutely safe, that the application is quite simple, and that it should prove most useful in the treatment of many of the diseases of children.

### 15. Ultra-violet Ray Treatment of Tuberculosis.

H. J. GERSTENBERGER and S. A. WAHL (*Journ. Amer. Med. Assoc.*, November 22nd, 1924, p. 1631) review the treatment of peritoneal and glandular tuberculosis in children by ultra-violet rays during the last few years. They think that since these rays penetrate only to a depth of from 0.5 to 1 mm. the principal action must be indirect, except in cutaneous tuberculosis. This indirect action has been confirmed by Hulschinsky's observation, the bones of one arm of a rachitic patient, after exposure to ultra-violet rays, becoming normal in outline. Jesionek cured a case of lupus by exposing to the rays the entire body, except the inguinal area. Rollier suggested that the pigmented epidermal cells converted these ultra-violet rays into longer rays with greater penetrative power. Kisch has shown, however, that bone tuberculosis can be improved by exposure to an intense light, such as reflected light from an acetylene-oxygen burner, which contains no ultra-violet rays. Some believe that the curative effect of the universal light bath is due to the luminous rays heating an appreciable portion of the total blood volume to a hyperpyrexial temperature, without causing an appreciable rise of body temperature. Balderrey finds that sunlight penetrates the human body to a depth of 10 inches, and that pigmentation is not merely protective: it lessens reflection and increases absorption of light. Gerstenberger and Wahl give their schedule of gradually increasing exposures, and details of ten cases of children

suffering from tuberculous adenitis, dactylitis, and peritonitis. Of these patients three died (two from tuberculous meningitis and one from miliary tuberculosis), two were improved, and five were apparently cured. A negress, aged 6, with peritonitis was successfully treated as an out-patient. They conclude that: (1) The sole use of ultra-violet rays has been of decided value in the treatment of peritoneal, glandular, and osseous tuberculosis. (2) Mesenteric glandular tuberculosis is the most rapidly improved; next comes mediastinal, and lastly peripheral glandular tuberculosis. (3) Pulmonary miliary tuberculosis, even in its early stage, is unaffected by ultra-violet ray therapy.

### 16. X-Ray Examination of the Spinal Cord.

H. PEIPER and H. KLOSE (*Klin. Woch.*, December 2nd, 1924, p. 2227) describe the methods employed to detect compression of the spinal cord by the injection into the cerebro-spinal fluid of substances which give a shadow on x-ray examination. Sclard and Forester introduced the method of injecting Iliodol, which, owing to its greater specific gravity, sinks in the cerebro-spinal fluid within the spinal dura mater, unless arrested by tumour or adhesions. The Iliodol can then be recognized, on x-ray examination, at the seat of the lesion. In place of Iliodol Peiper and Klose have used a special iodipin preparation made by Merck, 0.2 c.cm. of which was injected usually suboccipitally. Normally the injected iodipin sinks immediately to the end of the spinal dorsal sac. If arrested permanently at one point this point may be located by x-ray examination, and compression of the spinal cord by a tumour or the presence of meningeal adhesions is indicated. This method is also of service in the diagnosis of fractures of the vertebrae with compression of the spinal cord by bony splinters, and in the diagnosis of compression of the cord in tuberculous disease of the vertebrae. From their own observations (in fourteen cases) the authors conclude that a positive result with Sclard's procedure indicates definitely tumour, compression, or adhesions. In numerous cases also a negative result has proved correct in excluding compression. The x-ray examination after the injection of iodipin may give definite evidence of compression before the nervous symptoms are conclusive. Experiments on rabbits showed that the injection of iodipin might cause injurious effects on the spinal cord unless the quantity injected was very small. In man 2 c.cm. of 20 per cent. iodipin may be injected, according to the authors, without injury to the cord. They add that the new iodipin preparation of Merck should be employed since it is less irritating than other substances. They think that this method of diagnosis should only be carried out in large hospitals on the recommendation of a neurologist, and give a strong warning against its use in general practice, or by those who are inexperienced in such methods.

## Obstetrics and Gynaecology.

### 17. Treatment of Uterine Myomata.

BÉGOUIN (*Journ. de Méd. de Bordeaux*, November 25th, 1924, p. 903) discusses the scope of surgical treatment and of radio-therapy as applied to uterine fibromyomata. Certain of these tumours, he remarks, do not require either treatment. In illustration he quotes the cases of (1) a woman, aged 45, having a myoma the size of the foetal head; (2) a patient, aged 38, with a somewhat smaller tumour. The first patient was treated expectantly; during a laparotomy five years later the complete disappearance of the myoma was verified. The second tumour, although discovered accidentally and not causing symptoms, was treated radio-therapeutically. A few months later the myoma was found to be little diminished in size, but the patient developed distressing symptoms of a premature menopause. Béguin thinks that, especially towards the menopause, myomata which are not increasing in size and are not causing trouble require observation rather than treatment. Active therapy, on the contrary, is required for those which show progressive increase in size or lead to acute complications. Torsion, gangrene, suppuration, haemorrhage, or intestinal obstruction renders surgical intervention imperative; but when treatment is required by reason of increasing size or chronic symptoms, the problem of treatment by operation or radiation must be discussed. The latter stops haemorrhage at the price of castration, without destroying (although perhaps rendering smaller) the neoplasm, and with a negligible mortality risk; the former has a mortality of 3 to 5 per cent. (586 deaths among 12,833 operations in collected statistics presented to the October Congrès français de Chirurgie), but permits in some cases deliberately conservative measures. Between the two treatments, in some cases in which diagnosis is certain and no peculiarities of site or development afford special indications, the doctor

and the patient may choose according to their preferences—as, for example, in the case of a large interstitial myoma. In young women surgical treatment is in general preferable, as permitting ablation of the tumour and possibly the avoidance of castration, with preservation (in myomectomy operations) of the uterus. In aged patients also, Bégonin considers surgery prudent, for in them myomata which are not “silent” are to be suspected of malignant changes. He believes that at present there is too great a tendency among doctors, radiologists, and the laity to demand that myomata should first at any rate, as a trial, receive x-ray or radium treatment. With the improvement of radiological treatment there is now more than ever great need of careful diagnosis, not only between myoma and other morbid conditions, but also of the various alterations and complications of myomata. He concludes that the only cases in which radiological treatment is justified are those of myomata which towards the menopause increase progressively in size, lead to hæmorrhage, and are interstitial.

#### 18. Interscapular Pain in Interrupted Tubal Gestation.

C. MATHIEU and J. GUIBAL (*Bull. Soc. d'Obstét. et de Gynéc. de Paris*, 1924, 8, p. 661) describe the case of a 2-para, aged 27, who suffered from transitory abdominal pain and faintness a fortnight after missing a menstrual period; the pain recurred five days later and became increasingly severe. On the third day there was profound pallor, with asthenia; complaint was made of intense pain between the shoulder-blades. There was no vaginal hæmorrhage. Palpation of the right iliac region caused a recurrence of the interscapular pain. A ruptured tubal pregnancy was found with extensive intraperitoneal hæmorrhage. Pain between the shoulders has been noted by the authors in another similar case, and, like that in rupture of hollow viscera, such as the stomach, may be ascribed to sensory stimulation of the peritoneum, possibly in the region of the diaphragm.

#### 19. Pregnancy and Utero-adnexal Tuberculosis.

A. FRUHNHOLZ and P. FEVILLADE (*Gynéc. et Obstét.*, 1924, x, 5, p. 306) have been led by the following three cases to make a study of the relations between tuberculous disease of the uterus and appendages and the puerperal state: (1) bilateral tuberculous tubo-ovarian disease treated by conservative operation and followed by two abortions and a third gestation terminating in the birth of a nine months' healthy child; (2) pyrexia and adnexal inflammation occurring post partum, and thought to be due to ascending gonorrhoeal infection, but proved at operation twelve months later to be due to tubo-ovarian tuberculosis; (3) fever appearing within a day or two of labour, with gradual transition to the clinical appearances of tuberculous peritonitis. From their own observations and a study of the literature they conclude that the development of pregnancy is compatible with the existence of tuberculosis of the genital organs, even of the uterus; more usually the tuberculous disease precedes conception. Utero-adnexal tuberculosis and gestation may develop side by side, with or without affecting each other; in the former case the bacillary lesions may evolve with purely local signs suggesting ordinary inflammatory conditions, or be generalized (miliary tubercle). Genital tuberculosis may appear immediately or shortly after labour, taking an acute or chronic course, with or without eventual generalization; it is apt to be regarded as due to pyogenic bacilli or the gonococcus. At least six cases are recorded in which conservative, surgical, or medical treatment of utero-adnexal tuberculosis has been followed by pregnancy.

### Pathology.

#### 20. Production of Humoral Antibodies by Cutaneous Vaccination.

C. GERNEZ (*Ann. de l'Inst. Pasteur*, October, 1924, p. 892) has attempted to ascertain whether the inoculation of an antigen into the skin is able to give rise to immune bodies in the blood. His procedure was to inject red cells of the goat or human red cells into the skin of the rabbit, or alternatively to rub them into the epidermis, and then to ascertain the hæmolytic titre of the animal's serum after varying periods of time. In some cases single inoculations were made, in others repeated ones, but the principle was the same in each. The titre of the serum was determined by using a fixed dose of guinea-pig's complement, and varying the dilutions of the titre represented the minimal quantity of serum requisite to produce complete hæmolysis. Carried out on normal rabbits it was found that the serum contained a certain amount of hæmolysin for goat red cells, but none for human red cells.

The effect of injecting a single dose of goat red cells into the skin of the rabbit was to increase the titre of the serum from 7 to 30 times; repeated injections raised it from 25 to 120 times its initial value. The injection of human red cells led to the appearance of hæmolysins in the serum, but the quantity produced was not as great as when goat red cells were employed. In each case the greatest antibody production followed injection *en nappe*—a method whereby several doses of antigen are given simultaneously. When red cells were applied as a dressing to the shaved skin, thus inoculating the epidermis, the results were not so good. With goat cells the titre rose only 5 to 20 times, while in the case of human cells no hæmolysins were produced. Having shown that either the intradermal or the epidermal method of inoculation sufficed to give rise to the production of antibodies in the serum, he next proceeded to inoculate rabbits by the epidermal method and to remove the skin around the site of inoculation after varying periods of time. In this way he was able to show—using goat cells—that in order to prevent the appearance of antibodies it was necessary to remove the skin half an hour after the inoculation. He considers these results very conclusive; they are in direct opposition to those of Besredka, who claimed that cutaneous vaccination produced a local and not a humoral immunity. The author claims to have shown, in fact, that, whatever part these antibodies may play in skin immunity, there is no doubt about their appearance after cutaneous vaccination.

#### 21.

##### Bruck's Test for Syphilis.

M. MATSUO (*Dermatol. Woch.*, November 22nd, 1924, p. 1519) describes his modification of Bruck's flocculation test for syphilis. Matsuo uses two different extracts of human heart muscle in the proportion of 0.1 c.cm. dilute extract to 0.2 c.cm. serum, having found that an excess of extract is liable to vitiate the results in weakly positive cases. He examined 375 specimens of serum from 123 cases of definite syphilis, 78 cases of suspected syphilis, and 174 negative cases, and compared the results with those obtained by the Wassermann and Sachs-Georgi tests. The most definite agreement between the three sets of results occurred in the case of cerebrospinal fluid taken from patients with general paralysis; in tabes and cerebral syphilis the results were more variable. Matsuo concludes that: (1) In human serum the results of the three tests agree in the majority of cases, but Bruck's test often fails when the patient is undergoing a course of treatment. (2) In testing rabbit serum Bruck's test is more reliable than the other two tests, especially in known negative cases. (3) In human body fluids generally Bruck's test is less sensitive than the other two.

#### 22.

##### Protection against Anaphylactic Shock.

THE danger of injecting foreign serum into an animal which has been sensitized by a former dose are well known, and several methods of obviating it have been recommended. FERNBACH (*Monats. f. Kinderheilk.*, November, 1924, p. 27) questions whether results obtained with small laboratory animals are applicable to man, and reports a series of “desensitizing” experiments in children. Neufeld and Wedermann found that if a guinea-pig previously sensitized was given a very small (“desensitizing”) dose hypodermically it could endure, after an interval of three hours, the intravenous injection of a larger quantity of serum which would otherwise have been fatal; Besredka obtained the same result by a series of small graduated intraperitoneal doses. The human subject, as regards liability to anaphylactic shock, is second only to the guinea-pig, and both the single small dose and a graduated series of small doses have been recommended and used clinically as methods of desensitization. Ten children who were healthy, so far as could be determined, were sensitized by the injection of 0.1 c.cm. of horse or sheep serum intracutaneously; after an interval of eight or nine days the first secondary injection of 0.1 c.cm. intracutaneously produced in every case a distinct and typical local reaction. Secondary injections of the same amount were given intracutaneously every day, and when about the seventeenth day the local reaction seemed to have reached a maximum desensitization was attempted. Each child was given four “desensitizing” doses (0.1, 0.3, 0.5, and 1.0 c.cm.) at intervals of four hours, and the intracutaneous reaction tested as before for several days. In no case was any diminution of sensitivity found. Fernbach considers that these results show that the subcutaneous injection of small doses, recommended by Neufeld, Besredka, and others, does not bring about any “anti-anaphylaxis,” and affords no protection against the danger of a larger subsequent dose. Its only value is that in sensitized patients a local reaction will be seen which should put the physician on his guard; if any sensitivity exists intravenous injection must in all circumstances be avoided; carefully graduated doses may be given intramuscularly or subcutaneously.

# 

### Medicine.

#### 23. Infectivity of the Saliva of Tuberculous Patients.

OWING to the comparatively small number of systematic examinations which have been made of the saliva of patients suffering from tuberculosis of the lung, R. HOLLMANN (*Zeit. f. Tuberkulose*, 1924, 41, p. 127) has undertaken an investigation of the content of tubercle bacilli in the saliva of 74 patients. Swabs were taken from the lips, teeth, oral mucosa, tonsils, throat, and carious teeth at various times of the day; they were then spread out on slides and stained by Ziehl's method and sometimes by a modified Spengler method as well. No animal injections were made. He found that in 5 instances only (6.7 per cent.) of patients suffering from pulmonary tuberculosis were tubercle bacilli present in the mouth in sufficient quantities to be detected by a simple staining process. Of these 74 patients, 63 were relatively strong; in these bacilli were demonstrated only once—that is, in 1.5 per cent. On the other hand, in the remaining 6 patients, who were nearly moribund, they could be demonstrated four times—that is, in 67 per cent. It was shown, however, that this was due to the presence in the mouth of unexpected portions of sputum, which the patients were too weak to get rid of. Tests were also made of the tubercle bacillus content of droplets expectorated during coughing; in 13 out of 27 patients tubercle bacilli were found. In 50 patients he removed and examined the tonsils; in 7 instances they were found to contain tubercle bacilli, which were situated in the depths of the crypts, inaccessible to the saliva. Summing up, he concludes that since tubercle bacilli are only present in 1.5 per cent. of fairly strong and vigorous patients, and then only in small numbers, the saliva is of very little importance in the spread of tuberculosis. On the other hand, tubercle bacilli were found in about 50 per cent. of cases in which the cough spray was examined. This, then, would appear to be the most dangerous channel for infective material to take, and he concludes that it is against this source of infection that the most active measures should be directed.

#### 24. Pneumococcal Endocarditis.

E. A. LOCKE (*Boston Med. and Surg. Journ.*, November 13th, 1924, p. 913) thinks it probable that true pneumococcal endocarditis is a much rarer complication of pneumonia than has been generally supposed. Out of 11,243 cases of pneumonia collected by Probie, endocarditis occurred in 126 cases (1.1 per cent.). Locke has collected records of 835 fatal cases of pneumonia, 30 of which (3.6 per cent.) showed acute endocardial lesions, but in only 14 cases was the pneumococcus recovered from the vegetations. The incidence of pneumococcal endocarditis in this series was 1.7 per cent. Locke reports four typical cases; the patients were men in middle life, their ages being 45, 31, 51, and 34. The four cases terminated fatally in periods of thirty-one to fifty-three days, and in each case a pure culture of pneumococcus (Type I) was recovered from the valvular lesions. Each patient had a pseudo-crisis without there being physical signs of commencing resolution of pulmonary consolidation. In two cases no cardiac bruits were heard, in the others loud apical systolic murmurs were present. Locke adds that the endocarditis was of the proliferative or vegetative type, with less tendency to ulceration and destruction of valve cusps than is found in streptococcal or staphylococcal endocarditis. All the patients showed symptoms of a severe blood infection; in one case there was a localized pneumococcal meningitis, and in another case a large empyema developed, from which a pure culture of the pneumococcus was obtained. The meningococcal patient was treated systematically with anti-pneumococcal serum without any benefit.

#### 25. Renal Disease in Chronic Alcoholism.

F. VOGELIUS (*Acta Med. Scand.*, Supplement VII, 1924, p. 309) discusses the association of renal disease with chronic alcoholism and the difficulty of ascertaining whether this association is anything more than accidental. He has examined in hospital 42 patients, all of whom were confirmed alcoholics, and mostly admitted for treatment of their alcoholism. Strauss's functional test was carried out in the usual manner, two preliminary diet days being allowed before the test day, when 1,000 c.cm. of water were given in the morning, and only dry food was given for the rest of the day. The quantity, specific gravity, and salt excretion of each sample of urine collected every hour for the first part of the

day, and at longer intervals for the remainder of the twenty-four hours, were investigated. In 11 cases the action of the kidneys was normal. In 20 cases the quantity of urine excreted during the first four hours was very small, and the total excretion in the twenty-four hours was below normal, while the concentration of the urine was normal. The salt excretion ran parallel with the water excretion, and remained at about the same height throughout the twenty-four hours. In 11 cases certain other functional disturbances of the kidneys were observed. In several cases in which the test showed functional defects at the time of admission to hospital a repetition of the test after prolonged residence in hospital showed a restoration to normal of the action of the kidneys. In a few cases this return to normal persisted for years during which there was no abuse of alcohol. The author concludes that in most cases of chronic alcoholism the functional capacity of the kidneys is impaired, and that in a certain proportion of cases their functional capacity may be restored by reducing or abolishing the consumption of alcohol.

#### Syphilitic Aortitis.

B. KRÜGER (*Dermat. Woch.*, September 27th, 1924, p. 1141) states that syphilitic aortitis differs from atheroma in that the latter is chiefly a disease of old age and attacks men more frequently than women. Among 150 cases of atheroma treated in 1923 at the Port Hospital in Hamburg the largest number of cases were found in the sixth and seventh decades, whereas among 142 cases of syphilitic aortitis verified by post-mortem examination at the same hospital the majority were in the fifth and sixth decades, and cases in the fourth decade were more numerous than those in the seventh. The female sex was little affected by either form of aortic disease, but women were more frequently attacked by syphilitic aortitis than by atheroma. Difficulty in diagnosis sometimes arose, as atheroma not infrequently occurred in an aorta which had undergone syphilitic changes, being present in 49 out of the 142 cases. In contrast with atheroma syphilitic aortitis is circumscribed. It always begins in the thoracic aorta and usually above the aortic valves. In most cases the lesions extend to the diaphragm and then abruptly cease. In 27 cases syphilitic aortitis was complicated by aortic aneurysm, which in 9 instances was the cause of death by perforation. Syphilitic aortitis is a disease of the media, and in typical cases may assume one of two forms. Usually small-celled diffuse or focal infiltrations are found in the media, causing necrosis of the elastic fibres, and the adventitia and intima are secondarily affected. Less frequently nodular areas of infiltration, consisting of round cells, epithelioid cells, spindle cells, and giant cells, are present in the media and adventitia. It is only rarely that *Treponema pallidum* has been found in the aortic lesions.

#### 27. Intestinal Complications of Pulmonary Tuberculosis.

LAWRASON BROWN and H. L. SAMPSON (*Ann. de Méd.*, November, 1924, p. 381) point out that the commonest complication of pulmonary tuberculosis is intestinal tuberculosis, evidence of the latter condition being found in 50 to 80 per cent. or more of the autopsies held in cases of pulmonary tuberculosis. In the advanced stage the clinical signs are: Persistent diarrhoea, abdominal pain, tender points in the abdomen with or without rigidity of the abdominal wall, and the absence of symptoms suggesting acute abdominal trouble. The presence of the tubercle bacillus in the stools is of no diagnostic value, since 85 to 95 per cent. of these patients have the bacillus in the sputum. Diagnosis in the early stages is difficult. Digestive disturbances, especially constipation, or alternating diarrhoea and constipation, lack of improvement in the pulmonary condition, sometimes an amelioration of the pulmonary symptoms when the patient is obviously not doing well, irregular temperature, and considerable mental depression point to early intestinal tuberculosis. The only certain method of diagnosis is x-ray examination after a barium meal. A general irritability of the large intestine is evident, evacuation being complete, or nearly so, in twenty-four hours. The caecum and ascending colon empty themselves very rapidly, there is segmentation and dilatation of the coils of the small intestine, delay at the ileum, and gastric retention. These signs only indicate an intestinal ulceration, but when they complicate a case of pulmonary tuberculosis the diagnosis of intestinal tuberculosis can be accepted. The authors state that in the absence of diarrhoea medical measures are not indicated, but small doses of creosote in capsules with 1/4 grain of

Iodoform after food may be tried. In the later stages they recommend that cachets of salol and morphine, 2.5 grains of each, be given every four hours, and they find that calcium chloride, injected intravenously, is very effective in checking the diarrhoea. In the early stages excision is said to be the operation of choice, but the short-circuit operation is contra-indicated in advanced cases. They think that the best operation in the majority of cases is to fix the extremities of the affected portion of the gut to the abdominal wall so as to form two fistulae, thus regaining a healthy alimentary tract. Ultra-violet rays and heliotherapy are said to be of often value. Careful radiation of the intestinal tract with x rays may be tried.

28.

#### Hyalitis in Cerebro-spinal Fever.

R. METZ-KLOK (*Nederl. Tijdschr. v. Geneesk.*, October 25th, 1924, p. 2110), who records an illustrative case, states that hyalitis, or inflammation of the vitreous humour, is not infrequent in cerebro-spinal fever, its incidence ranging from 3 to 6 per cent. according to various observers. Meningo-coccic hyalitis differs but little from hyalitis found in pyaemic conditions, such as puerperal fever, endocarditis, and pneumococcal septicaemia. According to Uthoff, hyalitis in cerebro-spinal fever is usually unilateral; in only three out of twelve cases seen by him was it present in both eyes. The starting-point of the process is sometimes in the retina and sometimes in the choroid. Hyalitis in cerebro-spinal fever is metastatic and is not caused by spread of infection along the optic nerve. Metz-Klok's case occurred in a male infant of 4 months, who died after about a fortnight's illness. The right eye, which showed masses of greyish exudation in the vitreous, was enucleated after death, when a large thrombus was found in the central vein of the retina. The optic nerve anterior to the lamina cribrosa presented considerable oedema and slight diffuse cellular infiltration, but behind the lamina cribrosa the nerve showed little or no evidence of infection.

### Surgery.

#### Congenital Perineal Testicle.

S. G. SONNELAND (*Annals of Surgery*, November, 1924, p. 716) points out that the presence of a testis within the boundaries of the male perineum at birth is a rare occurrence. There are four classical varieties of congenital ectopia of the testis: (1) perineal, (2) interstitial, (3) penile, (4) femoral. The last of these is distinct from the others and extremely rare. In the perineal variety there is usually an accompanying abnormality of the corresponding vaginal process of peritoneum. No instance is known in which the vaginal process found its way into the scrotum while the testis went into the perineum. In most cases of perineal testis there is a predisposition to inguinal hernia, even if a congenital hernia does not already exist. With regard to the functional capacity of perineal testes, it appears that during early life, whatever their position, they have little influence on the development or general health of the individual. The reverse is true from the period of puberty onward, since they then assume the dual duty of forming the spermatozoa and elaborating the internal secretion. The treatment in view of this is extremely important. If the testis is allowed to remain in its abnormal position it will not undergo the cycle of changes incident to adolescence, and its procreative power will be lost; measures to correct the abnormal position should therefore be undertaken. At the age of 10 years, in the absence of complications requiring earlier operation, the testis should be brought into the scrotum. The author records in detail a case illustrating this rare anomaly.

30.

#### Non-gonorrhoeal Urethritis.

K. EDEL (*Nederl. Tijdschr. v. Geneesk.*, October 25th, 1924, p. 1966), who states that Boekhart in 1883 was one of the first to show that urethritis might be caused by organisms other than the gonococcus—such as streptococci—classifies non-gonorrhoeal urethritis into the following groups: (1) Cases in which no gonococci are found, but only streptococci or streptococci, if the patient denies having had gonorrhoea, and there is also no history of gonorrhoea and no gonococci are found, but the infection lasts several months; (2) cases in which no gonococci are found, but the condition has previously suffered from gonorrhoea, and the condition clears up in a short time; (3) cases without gonococci but with a previous history of gonorrhoea, in which the condition persists for several months; (4) cases which at first appear to be examples of non-gonorrhoeal urethritis, but in which gonococci are subsequently found. In the first two groups the appearances are quite distinct from those of true gonorrhoea.

The urethral discharge is not thick and creamy, but only slightly turbid and granular. There is usually little or no pain, and swelling of the urethral mucous membrane, oedema of the prepuce, and dorsal lymphangitis are absent. Complications, however, such as cystitis and epididymitis may occur, and the prognosis is not always favourable. As a general rule it may be said that when the symptoms do not clear up within a month the chance of recovery is doubtful. Edel found 12 cases of non-gonorrhoeal urethritis in a series of 169 cases of urethritis, so that the incidence of non-gonorrhoeal urethritis was 7 per cent.

31.

#### Surgical Treatment of Angina Pectoris.

P. K. BROWN and W. P. COFFEY (*Arch. Intern. Med.*, October, 1924, p. 417) describe the method adopted by them to relieve the pain of angina pectoris. Jonnesco's original operation consisted in removal of the left cervical sympathetic tract with its three ganglia and the first dorsal ganglion. They found that cutting the main trunk below the ganglion relieved the one causing death. In a few cases which was apparently the one causing death. Jonnesco only referred pains were not entirely relieved. The authors considered that this may be necessary in some cases where the symptoms are not completely relieved. Brown and Coffey believe that the main cause of angina is primarily a spasm of the thoracic, and perhaps also of the coronary arteries. The operation removes the cause of the anginal attack, and cutting it prevents the spasm. They suggest that their modified operation removes the cause of the anginal attack; to secure complete relief the operation may have to be bilateral. Sixteen cases are recorded of removal of the superior ganglion; in fourteen relief of the main symptoms was obtained, whilst two patients died.

32.

#### Myositis Infectiosa.

G. HOLM (*Acta Chir. Scand.*, October 10th, 1924, p. 415) gives an account of seven cases of infectious myositis treated in a surgical hospital in Upsala. He notes that it is difficult to draw a hard and fast line between the myositis infectiosa represented by "primary" acute purulent inflammation of a muscle and the metastatic myositis which represents a more or less generalized infection. The author prefers the definition, given to myositis infectiosa, of an acute purulent inflammation situated solely or primarily in a muscle. There may be a small insignificant non-pustular responsible for this rise to symptoms. Staphylococci were found in three cases, streptococci in one, a mixture of staphylococci and streptococci in one, and no organisms in one. There was also one case in which the abscess was spontaneously absorbed. With regard to the examination and diagnosis of such cases, the author stresses the misleading behaviour of the muscles in the neighbourhood of the abscess; by their contraction they may almost hide the existence of a large abscess, and it may only be when a general anaesthetic is given that complete relaxation of the muscles is effected and the true state of affairs ascertainable.

33.

#### The Etiology of Volvulus.

B. WEKSNER (*Zentralbl. f. Chir.*, September 27th, 1924, p. 2129) states that, in the academic year 1921-22, 12 cases of volvulus, in 5 of which the small intestine was involved, were seen at the surgical clinic at Yokaterinoslav, Russia. Such a large number is unusual even in big clinics. Rubinitis in the course of ten years saw only 10 cases of volvulus of the sigmoid at Prague, Ranzi in three years' experience in Eiselsberg's clinic in Vienna saw only 1 case, and Finsterer saw only 4 cases in ten years in the Russian clinics. The figures from the small intestine, which include cases of Martynoff's clinic at Moscow only one case occurred in the years 1908-9, and the same applies to Bobrow's clinic. Weksner attributes the frequency of volvulus at Yokaterinoslav to starvation. General loss of fat led to the abdominal wall becoming lax, the abdominal cavity contracted as well as the loss of fat in the mesentery. These were the cause of the intestine being extraordinarily movable. Moreover, the coarse quality of the food, to which many were not accustomed, gave rise to an increase in intestinal disease. The indigestible food, often taken in large quantities, produced a violent peristalsis, and, owing to the increased freedom of movement of the gut, volvulus readily ensued. Flatulence, which has recently been an almost universal disorder in Russia, was another factor in the production of volvulus.

## 34. Perforative Peritonitis in Paratyphoid Fever.

E. CORNILLIS (*Deut. Zeit. f. Chir.*, October, 1924, 5 bis, 6 Heft, p. 423) records an illustrative case of perforative peritonitis in paratyphoid fever, and has collected eight others from the literature, to which may be added that recently recorded by A. E. Mortimer Woolf (*ERITOME*, August 4th, 1923, No. 98). While as a general rule perforative peritonitis is a very serious condition in typhoid fever, and is usually fatal in spite of laparotomy, six of the ten cases of perforative peritonitis in paratyphoid have ended in recovery, although a comparatively long period has sometimes elapsed between the perforation and operation—such as forty hours in Chevrier's case. This difference between the two diseases is to be explained first by the better general condition in paratyphoid; secondly, by the smaller size of the perforation; and thirdly, by the lesser degree of virulence of paratyphoid bacilli for the peritoneum. Cornillis's case occurred in a man aged 35, admitted to hospital with the diagnosis of appendicitis, owing to the sudden onset of pain in the right iliac region, nausea, and vomiting. He had been feeling tired and feverish for eight days, but had continued his work until the day of admission. On laparotomy purulent peritonitis was found, but the appendix, apart from a slight catarrh, was normal. Numerous ulcers, three of which had perforated, were seen in the ileum. The corresponding mesenteric glands were enlarged and soft. Owing to the danger of further perforations 12 cm. of the affected gut was resected and an end-to-end anastomosis was performed. Subsequent recovery was uneventful. Bacteriological examination showed that the case was one of paratyphoid fever B.

## 35. Surgical Value of the Red Corpuscles Sedimentation Test.

SONNTAG (*Zentralbl. f. Chir.*, October 25th, 1924, p. 2383) records his observations on sedimentation of the red corpuscles in surgery in a paper based on 500 patients aged from 10 to 75, who had been examined by Linzenmeyer's method in the surgical polyclinic of Leipzig University during the last year. The method is exceedingly simple as regards removal of blood, apparatus, technique, and estimation of results. A positive result is obtained as a rule in absorption of products of decomposition, including inflammation and malignant growths. He urges caution, however, since the reaction is always positive in menstruation, pregnancy, operations, wounds, fractures, anaesthesia, protein therapy, and intense inflammatory disorders. An absolute diagnosis naturally cannot be made by this means between certain diseases which give a positive reaction, such as mastitis and mammary cancer, or tuberculosis and syphilis of the lymphatic glands. The test, however, is of value for distinguishing between inflammatory diseases, especially syphilis, tuberculosis, and malignant growths, on the one hand, and a variety of diseases on the other. It is, therefore, particularly useful in diseases of the bones and joints and abdominal organs—as, for example, in the diagnosis between tuberculous arthritis and a loose body in the joint, between morbus coxae and Perthes's disease, flat-foot and tuberculous disease of the foot, renal tuberculosis and tumour and calculus, prostatic hypertrophy and prostatic tumour, oesophageal cancer and oesophageal diverticula, thyroid carcinoma and enlargement of the thyroid. The reaction is also of value in differentiating between inflammatory and functional diseases, such as hysteria and simulation. Apart from diagnosis it is of prognostic value in the diseases mentioned above, such as tuberculosis and syphilis, as well as in malignant growths, in which it indicates ulceration, metastases, or recurrences. Finally, the method can be employed for detecting latent infection before an intended operation. Although the reaction is not specific or constant, Sonntag finds it useful as an objective sign, especially as the normal values are constant and differ widely from the findings in pathological conditions.

## Therapeutics.

## 36. Hydnocarpus Esters in Leprosy.

E. MUIR (*Indian Journ. Med. Research*, October, 1924, p. 221) recommends the use of esters of hydnocarpus oil derived from *Hydnocarpus wightiana*, which is the commonest species of hydnocarpus in India, in the treatment of leprosy. Esters of hydnocarpus oil mixed with an equal quantity of pure olive oil are used, the dose ranging from 0.5 c.cm. to 10 c.cm. If the patient can stand 10 c.cm. without pain, the oil may be omitted and 5 c.cm. of the pure esters given. The injections are given either intramuscularly or subcutaneously. Intravenous injections, though they have the advantage of being almost painless, not infrequently produce unpleasant fits of coughing and sometimes are followed by considerable pain in the chest. The intramuscular injections are given into the

gluteal region and smaller doses into the deltoid. Subcutaneous injections may be given by infiltration under the skin or under the skin of the extensor surface of the limbs. The infiltrated area should be gently massaged, so as to distribute the mixture and hasten absorption. It is advisable to begin with small doses in patients who are in the second or third stage of leprosy, 1 c.cm. being given at first and the amount increased by 1/2 c.cm. at each dose. The injections are given twice a week. A patient in the second or third stage may tolerate injections of large doses for a long period without showing any reaction, and then the injection may be followed by a violent reaction manifested by pyrexia, swelling, erythema of quiescent lesions, and sometimes the appearance of fresh sores. The fever and other symptoms may subside in a few days, but whereas formerly large injections failed to produce a reaction, now even small doses are sufficient to produce one. Unless the reactions are too frequent and severe, this sensitization is probably beneficial, as repeated reactions lead to resolution of the lesions and new permanent lesions are not formed. The reactions, however, should be controlled by keeping a careful record of the temperature, as the first sign of sensitization is an increasing tendency for the temperature to rise and remain up after injection. If the temperature rises to 100° F. and remains up for more than twenty-four hours, the indication is that an excessive dose has been given, and the next dose should be less. But if the temperature returns to normal in twenty-four hours, the same dose may be continued. Muir adds that the therapeutic effect of the esters is enhanced by adding either creosote or thymol to the solution. The most satisfactory results are to be obtained in early cases. The length of treatment in different cases varies according to circumstances.

## 37. Treatment of Pseudarthrosis.

L. IMBERT (*Arch. de méd., cir. et esp.*, October 4th, 1924, p. 5) holds that when a bone is broken the site of the fracture acquires an important though transient function—namely, that of detaining the lime salts circulating in the blood and probably of elaborating them and thus forming a callus. The site of the fracture thus becomes converted into a focus of assimilation, transformation, and also elimination, so as to form a sort of new gland the function of which is to make a callus. If a fracture in a person without obvious taint does not become consolidated, the endocrine glands or the fracture itself cannot have supplied the necessary secretion. The indication in such cases is to correct this deficiency by injecting blood or serum from another person with a fracture in which consolidation is taking place normally. In contrast with the prophylactic use of serum in measles, in which the serum is taken from a convalescent patient, the blood is supplied by a person in whom the condition is still active, and contains what is probably not found in convalescent blood—namely, ferments necessary for the formation of callus. Hitherto Imbert has only used serum in these cases, because its employment is most convenient, but he is of opinion that whole blood should be used. The dose depends on the amount that can be obtained from a patient—namely, from 10 to 20 c.cm. The donor should not be suffering from any infectious disease, and should give a negative Wassermann reaction. It is best that he should not be either a child or an elderly person. At first Imbert used to give the injections in any part of the body, but his results improved as soon as he gave them near the fracture or into the actual site of the fracture. The injections should be repeated two or three times. The author states that a result may be observed during the first week, but if none occurs the injections should be continued and the donor changed if possible. No bad effects were ever observed from the use of the serum in these cases.

## 38. Treatment of Pericarditis.

F. KÜLES and H. SCHÜRMEYER (*Klin. Woch.*, November 11th, 1924, p. 2104) give a concise account of the treatment of pericarditis. Restriction of fluids sometimes aids in checking pericardial effusion. Cold applications locally are often agreeable to the patient, and local abstraction of blood (by leeches or cupping) is advised. Subjective cardiac symptoms may be relieved by salicylates, but morphine or opium is often required: morphine should be given by mouth or as a suppository, and not hypodermically. Digitalis is recommended by the authors in all cases—in large doses when symptoms of cardiac failure are marked, in small doses if such symptoms are absent. In pericardial effusion the question of paracentesis pericardii should be considered. It is justified when dyspnoea, cyanosis, small and intermittent pulse, and collapse indicate danger to life. These symptoms often develop suddenly, but may rapidly subside after a few cubic centimetres of fluid have been removed. Paracentesis is also indicated when a definite effusion is not being absorbed or is only slowly absorbed. The authors suggest that in

certain difficult cases paracentesis may be of service in deciding the diagnosis between pericardial effusion and a dilated heart. It is usually performed only after much hesitation, and often too late. They think that Curschmann's method is the best, the left fifth or sixth intercostal space being punctured, in the nipple line, or outside it. If the paracentesis reveals pus, pericardiotomy should be performed and the pus evacuated. The lowest lying part of the pericardium should be opened and the sac drained. They report that very good results are often obtained. They add that in mediastino-pericarditis, adhesions of the pericardial surfaces usually cause no trouble; but adhesion of the heart to the bony anterior thorax wall causes functional disturbances. In such cases cardiomyolysis (with removal of pieces of the fourth, fifth, and sixth ribs) may be of definite service.

### 39. Treatment of Neurasthenia by Manganese Cacodylate.

G. LEMOINE (*Bull. Soc. de Théor.*, November 12th, 1924, p. 274), who has studied the action of manganese for several years, states that manganese cacodylate is easily prepared by saturating pure cacodylic acid with very pure manganese hydrate. The salt thus obtained is readily soluble and can be injected subcutaneously. Lemoine has employed it in cases of anaemia, asthonia following acute disease, and nervous depression, with gratifying results. Examination of the blood showed that the drug usually caused an increase in the number of polymorphonuclear cells as well as of the eosinophils, and a much more rapid rise in the haemoglobin value and number of red corpuscles than under treatment by iron salts. Neurasthenic subjects, who in other circumstances would have required a much longer treatment, showed a complete transformation in four to six weeks. The injections were painless and the preparation was absorbed very quickly. When the doses had been repeated for a certain time the following results were observed: (1) An increase in muscular strength, as shown by the dynamometer, at first very transient, but later more persistent, and finally permanent. (2) Rise of the blood pressure, which is almost always low in neurasthenics. The rise varied, but as a rule it amounted to 1 to 3 cm. Hg in four to five weeks' treatment. (3) The appetite increased, the digestive function improved, the tongue became cleaner, and there was a very distinct gain in weight. (4) Examination of the urine showed an increase in the amount of urea excreted, probably owing to the improvement in nutrition, and diminution of the sulpho-conjugate ethers and indican. (5) Diminution of psychical and physical asthenia, which was replaced by a sense of well-being. Lemoine attributes the successful results to the oxidizing action of manganese on the organic refuse accumulated, which interferes with the proper working of the nervous system.

### 40. Treatment of Rickets by Ultra-violet Rays.

LESNÉ and DE GENNES (*Paris Méd.*, December 20th, 1924, p. 520) discuss the treatment of rickets by ultra-violet rays, and point out that beneficial results have been reported both from experiments on animals and also from clinical experience, with the latter of which they deal more particularly. The moderate degree of anaemia characteristic of rickets is, they find, greatly benefited by this treatment, the red corpuscle count rising rapidly to the normal. They have observed pseudo-leukaemic conditions, however, which have been unaltered, even though rapid healing was observable in the bones. It is possible that such graver forms of anaemia are to be attributed to multiple infection in these children. Good results were reported in the metabolism of phosphorus and calcium, and still more outstanding improvement was observable by radiological examination of the bones, even of the most advanced cases. As early as the fifth exposure to ultra-violet rays active calcification could be discerned, and radiographs showed that this process continued steadily until, after forty exposures, the cure was radiologically complete. Running parallel with these changes a definite and marked influence on the general health was demonstrable; the children ceased to be peevish, recovered their appetites, gained in weight, began to walk, and delayed teeth made their appearance. The authors suggest that the explanation of the action of ultra-violet rays may be found in their influence on the circulating blood in the capillary networks or on the cutaneous nerve endings. They suggest also that possibly there may be some intermediate action on the sympathetic system and the endocrine glands related to the improved metabolism of phosphorus and calcium. They conclude that ultra-violet rays are the most active and the most powerful treatment available for rickets in early childhood, and they suggest that the rays may be employed preventively, especially during the winter, in the case of children who show signs of a rickety tendency.

### 41.

#### Peptone Treatment.

E. BULMER (*Edin. Med. Journ.*, January, 1925, p. 31) reports the treatment by peptone therapy of twenty patients suffering from asthma, rheumatic conditions, or sciatica. A sterilized solution of peptone was used, a primary dose of 0.4 gram for a healthy man, and 0.3 gram for a woman, being given by the intragluteal route, with subsequent injections, at five or six day intervals, of twice the preceding dose. No more than three or four injections were usually required for cure. The dosage was regulated to obtain a reaction temperature of about 101° F. The intravenous route was tried, but seemed to be dangerous. Bulmer found that the best results were obtained in rheumatic or fibrositic conditions, and in certain toxic states such as urticaria. In view of the feeling of physical well-being that followed the reaction the treatment was tried in chronic mild melancholia, but without success. Details of the cases are given, and Bulmer reports that the contraindications for this treatment are marked debility, tuberculosis, diabetes, and advanced cardio-vascular disease, in the last case owing to the profound fall in arterial pressure during the negative phase.

## Diseases of Children.

### 42.

#### Hepato-splenic Disease in Children.

HANAU (*Monatschr. f. Kinderheilk.*, October, 1924, p. 54) describes four cases of cirrhosis of the liver with enlargement of the spleen in children, and discusses their etiology. The first case was that of a male child 2 months old, admitted to hospital on account of vomiting after meals and passing mucus and blood-stained stools. The abdomen was much enlarged and the liver and spleen were palpable; the child died a fortnight later from bronchopneumonia. The autopsy revealed no cause for the enlargement of the liver and spleen beyond the fact that the liver on section showed pronounced cirrhosis of the Laennec type. The second case was that of a female child, aged 1½ years, in whom an enlarged liver and spleen had been detected in the first month of life, and who had had jaundice for the first three months. When the child was admitted to hospital the liver and spleen were palpable and there were dilated veins on the surface of the abdomen. At the autopsy a week later the liver was found to have a bossed surface and a thickened capsule, and the spleen was much enlarged; the larger bile passages were normally patent. Microscopic examination of cirrhosis with fatty infiltration and cells. The third patient was a girl 6 with pallor and lassitude, and ended fatally two years later with paralysis of all four limbs. The blood picture was that of a moderately severe anaemia of the secondary type, and the urine contained much urobilin. The liver was markedly cirrhotic, and the bile passages were much thickened. The fourth child was a boy of 1½, who was known to have had an enlarged abdomen since he was 8 months old. The liver and spleen were palpable, the white blood cells were reduced to 2,000 per cubic millimetre, of which about 50 per cent. were myelocytes. Considering the etiology of these cases, in three of which hepatic and splenic enlargement appears to have come on during the first few months of life, Hanau discusses the following conditions: (1) Icterus neonatorum—never known to leave such enlargements; (2) Icterus catarrhalis—very rare in infants and having a very favourable prognosis; (3) Icterus gravis, which differs from these cases in being familial; (4) septic infection; (5) syphilis; (6) tuberculosis—all the tests performed were negative in each case; (7) congenital biliary obstruction—no evidence of this was found after death in three of the cases; (8) Banti's disease—to which the course of these cases did not correspond; (9) acholic jaundice—but jaundice and anaemia were not present together; (10) Wilson's disease—distinguished by the character of its nervous symptoms; (11) alcoholic cirrhosis—a diagnosis not supported by the history in any of the cases; (12) leukaemia—negated by the blood counts. He concludes that toxic and infectious causes cannot explain all cases of liver cirrhosis or hepato-splenic disease in children, but that there must be, apart from any definite malformation, a disease of the hepato-splenic system which is congenital.

### 43.

#### Buttermilk in the Feeding of Infants.

A. B. MARFAN, R. TURQUET, and ARIS (*Paris méd.*, November 1st, 1924, p. 353) advocate buttermilk in the treatment of debilitated infants who cannot be fed at the breast. Buttermilk is cow's milk deprived of the greater part of its butter fat and containing lactic acid due to the fermentation of lactose. The authors hold that lactic acid favours digestion and assimilation by stimulating alimentary secretion, particularly that of the pancreatic gland, increasing diastatic activity, lessening putrefaction, and regulating

intestinal peristalsis. This may be disputed, but it is generally accepted that lactic acid helps in the predigestion of casein. The authors add that buttermilk should be prepared with scrupulous cleanliness, have a total acidity, in terms of lactic acid, of less than 7 grams per litre, and be fairly constant in composition. They use concentrated buttermilk, which keeps well in sealed bottles. It is prepared by the addition of 40 grams of cane sugar and 10 grams of rice flour or wheat flour to the litre of buttermilk reduced to half that volume. The cane sugar and starch are added to increase its nutritive value and to make it more palatable. Its food value is stated as 500 calories per litre. The addition of an equal quantity of water makes it of the strength of ordinary buttermilk, but the authors find it an advantage to dilute it even further with lime water. They give a detailed schedule of feeding. When the debilitated infant has survived a month, and especially when its weight exceeds 6½ lb., ordinary milk, condensed milk, or dried milk is gradually introduced into the diet. On any sign of digestive disturbance buttermilk should again be exclusively used. The authors classify debility among newly born infants into three groups: 1st degree, slight, where the weight lies between 6½ and 5½ lb.; 2nd degree, serious—5½ to 4½ lb.; 3rd degree, grave—below 4½ lb. The mortality among the infants fed on buttermilk is in each group approximately 20 per cent. less than in the case of condensed milk.

#### 33. A Negative Wassermann Reaction in Syphilitic Infants.

G. ARDIAN (*Hygiene*, October 31st, 1924, p. 725) draws attention to the not uncommon association of a persistently negative Wassermann reaction with clinically active syphilis in babies. Since the beginning of 1916 he has systematically made serological examinations in all his cases of congenital syphilis, even when there could be no doubt of the diagnosis made on the clinical evidence. There were some cases in which the negative Wassermann reaction was only temporary; after an interval it was found to be positive, even though specific treatment had been instituted during this interval. It again became negative after treatment had been continued for some time. In these cases the negative Wassermann reaction first observed might have been the result of faulty technique, but this explanation was not applicable to the cases in which the reaction was persistently negative while the clinical evidence indicated activity of the disease. The author records seven such cases, in none of which could there be any doubt, from the clinical point of view, of the existence of syphilis in both mother and child. These 7 cases form part of a total of 73 cases of congenital syphilis, with clinical signs of activity, treated in hospital and private practice. The author refers to recent observations by French and German pathologists, who have found that the blood and cerebro-spinal fluid of newborn infants with obvious clinical signs of syphilis often give a negative Wassermann reaction. But these authorities have found that this negative reaction soon becomes positive. The point on which the author insists is that this negative reaction may remain so for a long time.

## Obstetrics and Gynaecology.

#### 35. Dysmenorrhoea.

D. H. WESSELS (*South African Med. Record*, November 22nd, 1924, p. 524) classifies dysmenorrhoea according to its etiology as (1) inflammatory, including the majority of cases, and (2) non-inflammatory, embracing congenital and acquired cervical atresia, polyp, and backward or downward uterine displacements. He considers prophylaxis to be important, and urges that *in vivo* vaginitis in children should be treated seriously; leucorrhoeal discharges before and after puberty should be regarded as pathological, and attention be paid to general hygienic conditions. Sedentary occupations should be avoided and early marriage encouraged, dysmenorrhoea being described as Nature's protest against the restrictions and social handicaps of modern civilization. Relief may be obtained by internal and external heat and sedatives, but early removal of the cause should be the main object of treatment, with a view to preventing extension of fibrosis and the development of chronicity. Thyroid and ovarian extracts may be useful, but are not curative. The author finds that the best results by dilatation and curettage are obtained by early operation, when inflammation has ceased, and when there is only a moderate amount of fibrosis. The unsatisfactory cases are those in which inflammatory irritation with fibrosis is still progressing or is advanced. Dilatation and packing with iodoform gauze or bipp, or ionization in early cases, is said to give the best results. In severe intractable cases radium, to stop menstruation, was found better than treatment by x rays or hysterectomy.

#### 46. Prophylactic Episiotomy.

D. DEUTSCHMAN (*Med. Journ. and Record*, November 19th, 1924, p. cl) for the prevention of perineal lacerations advocates a modified prophylactic episiotomy, which avoids mutilation of the perineal muscles and obviates rectoceles and cystoceles, which may occur after normal deliveries without any visible tears in the perineum. The operation should be performed as a prophylactic and not as an emergency measure, the incision being under control, and not in consequence of pressure of protruding parts or mechanical interference. Preceding the incision, and as soon as bulging of the perineum commences, three long loose sutures on a long curved needle are introduced about one-third of an inch apart through all the layers of skin, subcutaneous tissue, bulbo-cavernosus, levator muscle, and vaginal wall, beginning from the edge of the vulva, and following a semicircular course with the convexity upward, outward, and downward, in the direction of the fibres of the vaginal portion of the levator muscle. The sutures should be left loose so as not to tear during the perineal distension. As soon as the distension has reached a reasonable amount a curved incision is made, commencing at the edge of the vulval orifice at a point about half an inch above the fusion of the labia majora and minora, and directed upward, outward, and downward between the sutures to follow the course of the fibres of the vaginal portion of the levator muscle, thus causing it least injury and preventing rectoceles. Deutschman claims that such a round incision avoids the ill effects which may result from either a posterior longitudinal or anterior oblique incision; it should be unilateral on the side which is undergoing the greatest amount of pressure.

#### 47. The Early Diagnosis of Pregnancy.

X. BRONNICOFF (*Zentralbl. f. Gynäk.*, November 8th, 1924, p. 2474) has carefully investigated the phloridzin test in connection with the early diagnosis of pregnancy. It consists of administering a minute dose of phloridzin (0.002 gram intramuscularly) on an empty stomach. The patient then drinks some water and three examinations of the urine are made at half-hourly intervals. Sugar should appear in the urine only in the case of a pregnant woman. The author quotes many statistics indicating that a positive reaction may be expected in 90 per cent. of the cases. He then quotes his own figures, which are as follows: women pregnant less than two months, 74 per cent. positive; non-pregnant women, 4 per cent. positive. He found that menstruation sometimes altered the reaction; in one case the test became positive from four days before till ten days after the period. In eight cases of amenorrhoea (not due to pregnancy) he found five positive. He also made tests on men, and here he got positive results in 72 per cent. of cases. He also gives figures for cases of complete and incomplete abortion and in women after the menopause. Accordingly Bronnicoff comes to the conclusion that the phloridzin test is not reliable, and that the problem of the early diagnosis of pregnancy remains yet to be solved.

#### 48. Incomplete Abortion.

J. A. VAN DONGEN (*Nederl. Tijdschr. v. Geneesk.*, November 15th, 1924, p. 2465) states that in a series of more than 2,000 cases of abortion during the last eight years 110 patients were examples of incomplete abortion complicated by infection of the adnexa, parametrium, peritoneum of Douglas's pouch, or diffuse peritonitis. In some patients the infection was present in several foci. Salpingo-oophoritis was found in 50, parametritis in 60, pelvic peritonitis in 27, and diffuse peritonitis in 26; 86, or 78.2 per cent., had an axillary temperature above 100.4°, and 24, or 21.8 per cent., below that level, as compared with 24.8 per cent. febrile and 75.2 per cent. afebrile cases in a series of uncomplicated abortions; 32 cases, or 29 per cent., were examples of criminal abortion by their own confession, though undoubtedly the real number of such cases was considerably higher, as even in the uncomplicated cases a history of this kind was obtained in 8.3 per cent. The duration of treatment till the patient's discharge or death ranged from one day to three months, the average being about five weeks, as compared with an average of 11.25 days in uncomplicated cases. The mortality was 23.6 per cent. (26 deaths), as compared with a mortality of 0.4 per cent. in uncomplicated cases without fever and 1.09 per cent. in uncomplicated febrile cases. In 56 cases curetting was performed. In 25 of these cases there had been bleeding, which in some instances had been very severe; in 23 remains of the placenta could be felt by the finger inserted through the cervix; and in 6 curetting was performed at the same time as posterior colpotomy. In some cases there was no haemorrhage, remains of the placenta could not be felt, and curetting was carried out as a last resort. In 34 cases a considerable quantity of placental residues was removed, and in 21 little or none. In 20 cases a surgical operation was carried out,

posterior colpotomy being performed for abscess in the pouch of Douglas, pyosalpinx, or abscess in the parametrium in 16 cases, and in 4 cases an encapsulated intraperitoneal abscess or parametric abscess was opened. The mortality in the non-febrile cases which were curetted and the non-febrile cases which were not curetted was nil, showing that the mortality was not connected with the operation but with the severity of the case. The mortality of the febrile cases which were curetted (32 per cent.) was somewhat higher than that of the febrile cases which were not curetted (27.8 per cent.). The author concludes that curetting should with few exceptions be carried out whenever there is reason to suppose that any portions of the placenta are left behind.

## Pathology.

### 49. Titration of Antidiphtherial Serum.

A. SORDELLI and R. SERPA (*C. R. Soc. de Biologie*, November 14th, 1924, p. 1043) have made a comparative study of the titration of antidiphtherial serum by Ramon's and by Ehrlich's methods. In the former case the method was slightly modified, the amount of toxin used being reduced to 5 c.cm. The antitoxin was diluted 1 in 10 with saline, and placed in varying amounts in a series of tubes. To each tube 5 c.cm. of toxin were added and incubation carried out in a water-bath at 37° C. The tubes were examined at short intervals, and the first which showed flocculation was taken as the index of neutralization. In their first experiments they tested two antisera against two toxins, and found that in each case the first flocculation always appeared in the tube containing 0.7 c.cm. of serum, in spite of the difference in the antitoxic titre of the two serums. It was expected to find flocculation occurring first in those tubes in which the quantity of serum multiplied by the antitoxic titre would have given the same figure; this, however, was not the case. Their results were not improved when, instead of taking the first tube in which flocculation appeared as their index, they estimated the limit of flocculation. They found also a difference in the antitoxic titre of the serum depending on which toxin was used for estimation; with one toxin the results were higher than with another. They consider that the use of Ramon's method should be deferred till it is possible to standardize the reagents.

### 50. Excretion of Tubercle Bacilli by the Bile.

TUBERCLE bacilli have often been demonstrated in the bile of men and animals, but the proportion of cases in which they may be found and the mechanism of their excretion by this channel are still subjects of debate. T. KOIZUMI (*Zeit. f. Tuberk.*, 1924, 41, p. 173) has investigated the bile in 50 human cases, examining it for tubercle bacilli microscopically and by cultural and animal tests. In all cases the bile appears to have been obtained at autopsy by opening the gall bladder, sucking out the bile, and adding to it the scrapings of the walls. For microscopical examination the bile was centrifuged and the deposit stained by the Ziehl-Neelsen method. In only one of the 50 specimens was the tubercle bacillus found. The author supposes, therefore, that the bile acts as a protective colloid, preventing the stain from being absorbed by the organisms. Cultures were made by the deposit with 15 per cent. sulphuric acid for thirty minutes, centrifuging, washing well, and planting in potato. In only one out of the 20 specimens examined by this method was the tubercle bacillus found. For animal experiment the centrifuged deposit was washed carefully and injected subcutaneously into the animal, presumably the guinea-pig. Out of the 50 specimens tested 23 gave rise to tuberculosis. It was noted that the bile of those patients whose liver appeared normal to the naked eye proved virulent more often than the bile of those patients who were affected with miliary tuberculosis—54.6 per cent. as against 40 per cent. In 12 cases the livers of patients of the first class were examined histologically, and lesions were found in no fewer than 11 of them. This observation gives strong support to Loewenstein's belief that towards the later stages of tuberculous disease the blood stream is invaded by tubercle bacilli, and that every death from tuberculosis is accompanied by a true bacillæmia.

51. Manganese and the Production of Immunity.  
C. E. PICO (*C. R. Soc. de Biologie*, November 14th, 1924, p. 1049) has attempted to confirm the report of Walbaum and March of an increase in the antibody production of animals injected with manganese chloride. After immunizing a horse with

diphtheria toxin, he waited a week and then injected manganese chloride on three consecutive days. The titre of the serum in antitoxin was estimated before and after the injection. The average increase in titre brought about by the manganese was 17 per cent. With tetanus antitoxin the manganese injections proved to be useless. In the case of antimeningococcal serum he found that the manganese had no effect on the agglutinin titre, but it increased the antibody production as tested by the fixation of complement. His results with precipitating serums were negative. The injection of manganese appeared to have some value in protecting sensitized guinea-pigs against anaphylactic shock. His conclusions are that while manganese chloride is able to raise the antitoxin titre of horses immunized to diphtheria toxin, it has no effect on those immunized with tetanus toxin, nor on the serum of animals containing precipitins, agglutinins, or haemolysins.

### 52. Tissue Resistance and Permanent Immunity.

EXPERIMENTS have been conducted by S. NUKADA and T. MATSUZAKI (*Journ. Exper. Med.*, November, 1924, p. 651) to determine the nature of the tissue alterations during the acquisition of immunity. They point out that there are two groups of diseases: (1) those to which a permanent immunity can be obtained either by an attack of the disease or by vaccination, such diseases being small-pox, scarlet fever, and typhoid; and (2) those to which no lasting immunity can be obtained; such diseases are influenza, gonorrhoea, and pneumonia. They remark that it is generally held that the development of permanent immunity is due to the presence of antibodies which have a specific effect on the causative organism of the disease, but they doubt this explanation, on the twofold ground that no strict relationship is demonstrable between the degree of immunity and the quantity of antibodies existing in the blood, and that immunity can often be shown to be present in the entire absence of circulating antibodies. They therefore directed their attention towards the tissues. The action of a solution containing the toxic products of the typhoid bacillus was tested on the heart of a normal rabbit—isolated from the body and perfused with Locke-Ringer fluid—and on the heart of a rabbit which had been immunized by several doses of a typhoid vaccine. They found that the immune rabbit heart continued to beat for considerably longer than the normal rabbit heart. Having demonstrated the increased resistance of the former, they proceeded to ascertain whether this was specific. For this purpose they tested the effect of the typhoid toxin on the hearts of animals immunized to other organisms, such as *B. coli*, *B. influenzae*, *B. pestis*, and others. Their results showed that the hearts of these animals were not specially resistant, and it was concluded that the resistance of the hearts of animals immunized against *B. typhosus* must be specific in its nature. This specificity might be due to the presence in the heart substance of a definite antitoxin to the typhoid bacillus, or it might be the result of a specific biological alteration of the tissue cells. Failing in further aim any evidence in favour of the first, they consider that the second must be correct. Therefore, is that permanent acquired in typhoid—is due, not to the presence of a definite and specific change in the tissue cells resulting in an increase of the resistance of the tissue to the toxic products elaborated by the causative organism.

### 53. Estimation of Sugar in the Blood.

A SIMPLE method of estimating sugar in the blood, eminently suitable for use by medical practitioners, has been described by E. G. B. CALVERT (*Biochem. Journ.*, 1924, xviii, No. 5, p. 839). It consists in withdrawing 0.16 c.cm. of blood from the thumb by means of a specially graduated pipette, mixing it with 7.3 c.cm. of distilled water, and adding a 10 per cent. solution of sodium tungstate followed by sulphuric acid. The total volume reaches 8 c.cm. As soon as the proteins are coagulated the fluid is filtered through paper, and 5 c.cm. of the filtrate are used for the subsequent examination. To this 5 c.cm. are added 2 c.cm. of an alkaline copper tartrate solution, and the mixture is placed in a boiling water-bath for six minutes; it is then withdrawn and treated with 2 c.cm. of phosphomolybdic acid solution, which produces a blue colour. A standard sugar solution is treated in the same way so as to serve as a comparison. Both solutions are allowed to stand for four minutes, cooled, and made up to 12.5 c.cm. with distilled water. The colours are then compared in a colorimeter, and from the readings obtained the calculation. The method is stated to be quite simple, and the author is satisfied of its accuracy.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 54. Complete Remissions of Pernicious Anaemia.

O. LINDBOM (*Acta Med. Scand.*, Supplement VII, 1924, p. 339) has followed the blood changes during a year in about 50 cases of pernicious anaemia sent him for examination by medical practitioners. He usually found no difficulty in demonstrating the characteristic blood changes even when the clinical improvement was such as to deserve the description of a remission. Even in the cases in which the number of erythrocytes rose to 4 or 4½ million, a raised colour index and definite megalocytosis were demonstrable. There were, however, three cases in which the examination of the blood, as well as the clinical examination, temporarily showed a perfectly normal condition. One of these patients was a married woman, aged 59, who was first examined by the author in March, 1922, when she had suffered for a year from characteristic symptoms of pernicious anaemia. The haemoglobin was 65 per cent., the erythrocytes numbered 2,450,000 per cubic millimetre, the colour index was 1.3, and there was marked megalocytosis, leucopenia, neutropenia, and thrombopenia. The spleen was palpable, and there was a marked urobilin reaction. Under dieting, rest in bed, and treatment with arsenic, she improved rapidly, and in May and June she not only felt perfectly well, but the haemoglobin was between 85 and 100 per cent., the erythrocytes numbered from 4,250,000 to 4,830,000, and the colour index was between 0.9 and 1; none of the morbid cells indicative of pernicious anaemia could be found. The disease, with its characteristic blood picture, soon returned, however, and death occurred in August, 1922.

### 55. Second Attacks of Measles.

Loos (*Wien. Klin. Woch.*, September 26th, 1924, p. 981) discusses the possibility of second attacks of measles, and records the following three cases which came under his observation. In the first case the child was brought to hospital with undoubted measles, the mother stating that the child had had a previous attack in the same hospital six months before. On consulting the notes, however, it was found that the first attack was rubella. The second case was in a member of a family of nine children who contracted measles at the same time. A year later one of the children, aged 8, developed measles. It was at first thought that this was a second attack, but on careful inquiry it was found that this was the only child who had escaped in the family epidemic in the previous year. The third case was in one of Loos's assistants, who had had an undoubted attack of measles in childhood at the same time as his sister. The eruption on the second occasion, which was at first supposed to be measles, was probably only a drug eruption occurring in influenza. Loos therefore, without denying the possibility of second attacks of measles, has not yet seen an undoubted example, and maintains that all supposed cases require critical investigation.

56. H. W. BERINSON (*Nederl. Tijdschr. v. Geneesk.*, October 11th, 1924, p. 1864) states that in a series of 903 cases of measles in his practice only 16 (1.7 per cent.) gave a history of a previous attack. Of these, 4 were in the first year of life, 7 were between 1 and 3, and 5 between 3 and 7. A second attack of measles would therefore appear to be most frequent in the first year of life, although the incidence of the disease is lowest at that age, only 80 of the 903 cases being under 1 year. The interval between the first and second attacks varied in different cases.

### 57. Cardiac Effects of Atropine.

R. D. RUDOLF and F. M. R. BULMER (*Amer. Journ. Med. Sci.*, November, 1924, p. 641), from a study of some of the cardiac effects of atropine, point out that a small dose acts in an opposite way to a large dose. Small doses slow the heart rate through stimulation of the vagal centres, whereas large doses, by paralyzing the vagal cardiac endings, cause acceleration. Single doses of 1/100 grain cause slowing of the pulse rate together with lowered blood pressure, the effect lasting for several hours. In a few cases such a dose caused little or no slowing, or even hastening, but the subsequent administration in such individuals of a still smaller dose always produced slowing. Heart-block, due to digitalis or other causes, was found to be increased by small doses of atropine, but large doses tended to remove it. In average

doses no change in the rate occurs, since the two effects of stimulation of the vagal centres and partial paralysis of the cardiac nerve endings neutralize each other. The authors found that individuals varied considerably in their reaction to atropine, but in most adults 1/100 grain would as a rule only slow the heart.

### 58. The Dick Test in Scarlet Fever.

A. ZINGHER (*New York State Journ. Med.*, November, 1924, p. 915), who has made trial of the Dick test in over 7,000 cases, has come to the following conclusions: (1) It is a reliable method for determining susceptibility and immunity to scarlet fever. There were only eight positive reactors, and none of the negative reactors developed scarlet fever. (2) The test indicates susceptible persons who need immediate passive immunization with scarlet fever antitoxin. The rapid appearance of the reaction in eight to twelve hours is of great value for this purpose. (3) The test helps in the diagnosis of doubtful cases. A strongly positive reaction early in the disease and again later in convalescence contraindicates the diagnosis of scarlet fever. A definitely negative reaction during the first two days of the rash is also against this diagnosis. (4) Active immunization with scarlet fever toxin is safe, and is not accompanied by constitutional symptoms if the dose of toxin is gradually increased. The skin test dose is a convenient method of measuring the amount of toxin. For children under 3 years the doses are 100, 250, and 500 skin test doses. Over 3 years and up to 12 years the third dose is gradually increased up to 500 skin test doses. For adults the dose may be increased up to 1,000 skin test doses. (5) Purification of the toxin by the sodium chloride and acetic acid precipitation method gives a preparation which is better for the Dick test and for active immunization owing to lesser protein reactions. (6) The use of toxin treated with formaldehyde to make it practically non-toxic and of toxin-antitoxin mixtures represents further steps in the development of active immunization against scarlet fever. (7) The Dick test applied to 232 cases of scarlet fever showed that 91.3 per cent. gave positive reactions during the early stage of the disease and negative reactions in convalescence; 19 patients gave a persistently positive reaction, of whom 2 developed scarlet fever subsequently, and 12 of the remaining 17 did not desquamate. (8) Probably most of the strains of scarlet fever streptococcus produce a single toxin. The few cases which show a positive Dick test in convalescence and yet desquamate point either to an insufficient amount of antitoxin in the patient's blood and tissues to neutralize the action of the toxin in the test or to the production of more than one toxin by a few exceptional strains of the scarlatinal streptococcus. (9) The scarlet fever toxin is neutralized in multiple proportions by the antitoxin.

## Surgery.

### 59. Treatment of Naso-pharyngeal Fibromata.

E. SCHEMPP (*Zentralbl. f. Chir.*, October 11th, 1924, p. 2232) states that the surgical treatment of naso-pharyngeal fibromata entails considerable disadvantages and dangers. Not only is an extensive operation required to reach the base of the tumour, but owing to its rich blood supply its removal is usually associated with severe haemorrhage, which in a number of cases has proved fatal. If plugging the naso-pharynx is required to check the haemorrhage, hearing may be impaired, and even after the tumour has been successfully removed recurrences are extremely frequent. For these reasons, and also because naso-pharyngeal fibromata tend to disappear spontaneously after the body has ceased to grow, treatment has been more conservative of recent years. Attempts have been made to reduce the size of the growth by partial operation or to make it shrink by canterization, diathermy, or electrolysis, but these methods are not very satisfactory. In partial operations haemorrhage always has to be considered, while electrolysis requires considerable time and patience on the part of both the doctor and the patient. Since 1918 all the patients with naso-pharyngeal fibromata attending the surgical clinic of Professor Perthes and the oto-rhino-laryngological clinic of Professor Albrecht at Tübingen have been treated with x rays. In 7 out of 9 cases the results were excellent, so that the patients became more or less completely free from symptoms; one patient was lost sight of after considerable improvement, and

in one case the improvement was less striking but nevertheless definite. Diminution in size of the growth began in one or two weeks, and as a rule became quite distinct at the end of four weeks. The shrinkage still continued for some months after the last application of x-rays, and in no instance was an increase in size observed, even a long time after the applications had ceased. No serious bad effects were observed. In only the first case did slight atrophy of the skin result; in other cases there were a transient dryness of the skin and loss of hair, but telangiectases never occurred. There were no bad effects from irradiation of the hypophysis, which was inevitable in these cases. He adds that the only drawback of x-ray treatment is that the good effect always takes a little time to appear, but this delay is compensated by the advantages of the method, which can be recommended as the one of choice for dealing with nasopharyngeal fibromata.

#### 60. Cholecystectomy for Typhoid Carriers.

J. A. VOSS (*Acta Med. Scand.*, Supplement VII, 1924, p. 360) gives an account of four cases in which cholecystectomy was performed, and the removal of the gall bladder, found to be infected with typhoid or paratyphoid bacilli, was followed by sterilization of the stools so far as these organisms were concerned. In two cases, however, typhoid or paratyphoid bacilli had not been demonstrated in the stools before the operation; in both these cases the operation was performed because there had been attacks of bilious colic, and in one case there was not even a history of typhoid fever. Yet a bacteriological examination revealed paratyphoid bacilli in one case and typhoid bacilli in the other. In the other two cases, also, cholecystectomy was performed because the patients were suffering from cholecystitis and not because they were carriers of typhoid or paratyphoid bacilli. The author admits that he had been sceptical as to the value of attempting to sterilize carriers by removing the gall bladder, but his more or less accidental experiences in this matter, together with a study of the literature of the subject, have converted him to the view that this procedure may be justifiable in carefully selected cases. His summary of the literature includes seventy-three cases, in about three-quarters of which success was achieved with cholecystectomy or cholecystostomy, or the one operation followed by the other. About half of the cases of paratyphoid carriers were thus treated with success, whereas four out of every five typhoid carriers were effectively cured. Cholecystectomy or cholecystostomy, in this series of seventy-three cases than did cholecystostomy. Voss has no hesitation in recommending early operative treatment when a patient with a history of typhoid or paratyphoid fever shows the smallest signs of cholecystitis; for the cases in which there is no such evidence he notes that the dangers of cholecystectomy without inflammation are no greater than those in the case of appendectomy.

#### 61. Cancer of the Oesophagus.

H. J. J. BLADWIKIP (*Nederl. Tijdschr. v. Geneesk.*, August 30th, 1924, p. 1131) records his observations on 125 cases of cancer of the oesophagus which occurred at the municipal hospital in Amsterdam; 112 were in males and 13 in females. Their ages ranged from 30 to 90, but 91 cases occurred between 50 and 70. Examples have been reported by Guisoz at 14, 22, and 24. The distribution of the lesions was as follows: Upper third of oesophagus, 28 cases; middle third, 51 cases; lower third, 44 cases; doubtful, 1 case; upper and lower third, 1 case. In 13 metastases of various sizes were found in the wall of the oesophagus. They were usually situated beneath the mucous membrane in the neighbourhood of the primary tumour, but sometimes 15 cm. distant from it. In one case the primary growth was at the level of the cricoid, and the metastasis was just above the cardiac orifice. In 4 cases metastases were found in the wall of the stomach. Metastases in the liver were found in 3 of the cancers in the middle third, and in 17 of those of the lower third. In 69 cases the oesophageal growth had perforated or become adherent with neighbouring organs. In 80 cases metastases were found in remote organs, and in 59 there were metastases in the lymphatic glands. In 49 cases, or about one-third of all the patients, the process remained localized on naked-eye examination.

#### 62. Chauffeur's Fracture.

J. GROSSMAN (*Amer. Journ. of Surg.*, November, 1924, p. 261) considers the term "chauffeur's fracture" should be discontinued, being a misnomer which does not indicate the type of fracture present. No definite type of fracture results from trauma indicated while cranking an automobile; the term merely indicates the manner in which the fracture has been sustained. Fracture may result from indirect violence due

to "kick-back" from the handle at the height of compression, so that the ball of the thumb is jammed backwards, or from direct violence, the rotating handle striking the forearm. He records fourteen cases illustrating various kinds of fractures. These include different varieties of fracture of the lower end of the radius; in three there was an associated fracture of the ulnar styloid process. In others there was a fracture of the base of the thumb metacarpal. Grossman concludes that in spite of self-starters fractures resulting from cranking motors are not at all uncommon.

## Therapeutics.

#### 63. Radium and Mesothorium in Graves's Disease.

F. GUDZENT (*Klin. Woch.*, December 16th, 1924, p. 2329) records that between 1910 and 1914 he treated patients with Graves's disease with small doses of radium and obtained striking results. At first the condition became worse, then marked improvement followed. Other investigators published good results subsequently, but the author thinks sufficient attention was not paid to the small dose of the radium rays required. He now records his results during the last four years in 35 cases, 10 of which presented marked signs of Graves's disease, but in 25 early signs only were present. After the treatment 19 cases were traced, and short notes are given. In 13 of these cases one radium exposure caused the symptoms to disappear; in 6 the symptoms recurred after two to three months, but after a second exposure permanent good results were obtained in 4. In 2 cases a third radium exposure was required, the final results of which cannot yet be stated. The author concludes that Graves's disease and hyperthyroidism can be successfully treated with relatively small doses of the gamma rays (radium and mesothorium). These small doses cause no severe reaction, and the patient may return to his occupation at once. He finds the treatment free from danger, convenient, and inexpensive: it was especially suitable when operation was refused or when it was inadvisable on account of the cardiac condition. He thinks that only those cases must be excluded from the treatment in which signs of compression of the trachea are present, owing to the large size of the goitre. In such cases reactionary swelling of the goitre after the radium treatment might cause suffocation; and, in consequence of connective tissue changes, reduction of the size of the large goitre cannot always be satisfactorily obtained.

#### 64. Heliotherapy in the Treatment of Genito-urinary Tuberculosis.

N. A. MYLL (*Journ. Amer. Med. Assoc.*, December 6th, 1924, p. 1834) describes the treatment of fourteen cases of genito-urinary tuberculosis by means of heliotherapy on the lines advocated by Rollier. The genito-urinary lesions are regarded by Myll as being only local expressions of a generalized tuberculous infection. The patient is warned that the treatment will last for two years, so that he need not worry if immediate amelioration is not observable. Although the patients were confined to bed various occupations were encouraged, such as courses of study, typewriting, leatherwork, and basket-weaving. On the first day of treatment sunlight was applied for ten minutes; the feet and ankles were radiated, five minutes on the anterior and five on the posterior aspect. On the second day the exposure was lengthened to twenty minutes. Successive increases in time and in the body area exposed continued until the total time so occupied was two hours in summer and three in winter, the whole of the body, except the head, being finally treated in this way. The genitalia were intensively radiated, and special attention was paid to the sites of active inflammation. On sunny days artificial light was used; no burning of the skin was permitted. As a routine treatment, 5 c.cm. of a 5 per cent. solution of calcium chloride was injected intravenously, which relaxed the spasm of non-striated muscle and reduced the bladder irritability. The results were very encouraging. The general health and appetite were much improved; insomnia gave place to deep and restful sleep, and the previous irritability disappeared. The skin became evenly browned, and there was a stimulant effect on the hairs and on the sebaceous and sweat glands. Reactions occurred in superficial lesions, and these quickly commenced to heal under the tests and serotum were sometimes increased temporarily before drying up. Deeper lesions in the prostate and seminal vesicles yielded to treatment more slowly. In the case of less spectacular. Myll is convinced that heliotherapy is specially valuable in the treatment of genito-urinary tuberculosis.

## Dermatology.

## 65. Cutaneous Lymphadenosis.

A. GROSGLIK (*Dermat. Woch.*, November 8th, 1924, p. 1460) records a case of lymphadenosis cutis in a man, aged 38, which presented the following peculiarities: (1) The leukæmic growths were for a long time exclusively confined to the legs, which even at a late stage were their principal situation, whereas usually the face is the area of predilection for these tumours. (2) There was a pronounced spontaneous regression of some of the tumours. During the first year of the disease, according to Walther, leukæmic tumours as a rule show no tendency to subside. Felix Pinkus states that considerable absorption of the growths without degenerative changes only occurs in cases of acute leukæmia or in cases where septicæmia or other febrile diseases cause a complete change in the blood picture. In the present case there was a complete absorption of some of the tumours without any symptoms of acute leukæmia, septicæmia, or changes in the blood picture. (3) The blood picture was normal, the relation of the lymphocytes to the polymorphonuclear cells varied within normal limits, and there was not even a relative lymphocytosis. The case would best be described as one of leukæmic lymphadenosis of the skin. (4) The rapid cachexia which developed after intravenous injection of neosalvarsan and later after deep x-ray treatment, and the condition preceding death indicated, in spite of the absence of an autopsy, the presence of internal growths, which, like the skin tumours, rapidly increased in size and surrounded the large abdominal vessels. The clinical symptoms suggested necrosis of the internal tumours with involvement of a large vessel, death being due to internal hæmorrhage.

## 66. Erythema Nodosum and Tuberculosis.

H. J. VETTESSEN (*Norsk Mag.*, 1924, p. 947) discusses the as a precursor of tuberculosis insurance societies. A scrutiny of his records in the period 1905-22 of applicants for life insurance showed that there were 72 (38 males and 34 females) who gave a history of erythema nodosum. In 26 of these 72 cases no contract was signed between the applicant and the society, but of the remaining 46 persons as many as 10 developed tuberculosis after insurance was effected. The author does not claim that these figures are large enough to warrant general conclusions, but in the light of numerous other investigations indicating that active tuberculosis often develops soon after the outbreak of erythema nodosum he has advised the society not to accept applicants for insurance if they have suffered from erythema nodosum within four years of the time of application. He urges other life insurance societies to scrutinize the ultimate fate of those of their members who at some time or other have suffered from erythema nodosum.

## 67. Lupus and Syphilis.

MAX POPPER (*Dermatol. Woch.*, November 29th, 1924, p. 1545) observes that cases of a congenital combination of lupus and syphilis are more common than has generally been supposed. A differential diagnosis can often be made only after the discovery of spirochaetes or tubercle bacilli in sections of the infected skin. In some cases where the pathological conclusions are doubtful the diagnosis may be deduced from the results of antisyphilitic treatment or the Wassermann and von Pirquet tests. The site of the initial lesion may be of great diagnostic value, and also its appearance. Soft pulpy granulations or tubercles may be present; the "tubercloid" picture with the changes indicative of lupus will be seen in the majority of cases. Jadassohn was the first to recognize "lupoid" types in syphilis. Nikolaus and Favre have described typical cases of tertiary syphilis with actual tubercles or lupus granulations, in which each disease is indistinguishable clinically from the other. Popper arrives at the following conclusions: (1) Success in the treatment of "tubercloid" forms of syphilis depends largely on the presence of a high degree of skin resistance or of attenuation of the specific virus. These conditions may develop after the failure of previous antisyphilitic treatment or in any syphilitic infection occurring at the same time as an infection by tubercle bacilli. (2) "Tubercloid" syphilis is found in those sites where skin infections by tubercle bacilli commonly occur. (3) The differential diagnosis of tertiary syphilis and lupus can seldom be determined by clinical observation alone. (4) The histological findings, which before treatment show characteristic "tubercloid" tissue changes, later yield evidence of lowering of the abnormally high allergic condition; subsequent histological sections resemble those of tertiary syphilitic lesions.

## Obstetrics and Gynaecology.

## 68. Bradycardia in the Puerperium.

A. LANHARDT (*Schwed. med. Woch.*, December 11th, 1924, p. 1141) draws attention to the statement, to be found in almost every textbook of midwifery, that bradycardia is common in the puerperium; indeed, it is often mentioned as characteristic thereof. The author has made a study of the pulse rate during the puerperium of 5,000 women treated in his maternity hospital in the period 1917-21. The temperature of these women was always below 100° F., and there were no complications. In only 2 women was the pulse rate uniformly so slow as 60 or slower; only 15 women had a pulse rate uniformly below 70; and there were only 45, or less than 1 per cent. of the total, whose pulse rate was uniformly below 72. Even the number of women whose pulse rate was occasionally as low as 60 or less was small (334). It was found that a slow pulse rate was more frequent in the first ten days of the puerperium. On the evidence of these figures the author dismisses as fictitious the assertion that a pulse rate uniformly below 60 is a characteristic feature of the puerperium. He suggests that the presence of this statement in most textbooks is an example of the tendency of textbook writers to transcribe statements without checking their accuracy.

## 69. Milk Injections in Gynaecology.

G. GELLHORN (*Amer. Journ. of Obstet. and Gynecol.*, November, 1924, p. 535) affirms that protein injections stimulate fatigued cells, enabling them to renew their struggle against invading organisms; thus the affected organ or tissue may rid itself of disease. The simplest method of giving such injections is the injection of 5 c.cm. of sterilized milk into the gluteal region as a primary dose; when the patient is weak or has high fever a smaller dose should be given. The standard dose of 10 c.cm. is reached at the second or third injection, the injections being given at an interval of three to five days, according to the intensity of the reaction. The cases in which the injections were of the greatest use were those of acute and chronic salpingitis and of puerperal sepsis. In mild cases two injections sufficed, but in severe many more were required, the author's average being six. He warns that too many injections must not be given lest protein cachexia develop; this condition, however, has only been detected as yet in animal experiments. A general reaction occurred usually in from six to eight hours after treatment, the temperature rising as a rule to 100°-101°; the general condition was affected for only twenty-four hours at the most, after which time the patient felt much better and the appetite improved. A hyperleucocytosis of 20,000 to 25,000 was usually noted the day after the injection. In pelvic infection, especially when due to the gonococcus, the results were particularly good; adnexal tumours diminished steadily in size and might even eventually disappear. The tubes, uterus, and probably the bladder, were most favourably influenced by milk injections, whereas the ovaries were refractory. Exudates were absorbed, but adhesions were not affected. Gonococcal cervicitis, urethritis, and proctitis were not affected by the injections as a rule. Gellhorn considers that in obstetrics the injections may be of the greatest value in cases of sepsis; he adds that treatment should be begun early to give a full chance of success, though cases of severe and generalized sepsis are quoted which have yielded to the treatment. The injections are also recommended in puerperal pyelitis, and some investigators have recommended a prophylactic injection in all cases where a febrile puerperium is anticipated. Contraindications to this method of treatment include cardiac decompensation, diabetes, and alcoholism; Gellhorn is uncertain whether pregnancy should not also be included. Great caution should be exercised in cases of asthma, angioneurotic oedema, urticaria, epilepsy, or other grave nervous instability. He concludes by stating that milk injections must not be regarded as a panacea; indiscriminate use invites disaster, and is liable to bring discredit on a valuable method of treatment.

## 70. Combined Treatment of Cancer of the Breast.

M. DE BEULE (*La Gynécologie*, September, 1924, p. 517) does not accept the conclusions of Regaud and Perthes that the addition of radiotherapeutic measures to surgical ablation of cancer of the breast is useless or harmful. He admits that some early applications of radium were disastrous, but since 1921, in twenty-one cases in which the outlook appeared grave, he has used a combined x-ray, surgical, and radium treatment, which he thinks likely to lead eventually to good results. Pre-operative x-ray applications are directed to the breast, the supraclavicular and infraclavicular fossae, the internal paramammary region as far as the middle line, the inframammary region as far as the costal margin, and

the back as far as the middle line. From five to eight areas receive an erythema dose of 3,000 to 4,000 R. successively in six or seven days. The operation is performed about fifteen days later and the radium is applied at the same time. Through an incision 0.5 cm. above the clavicle the inferior third of the posterior triangle is cleared of glands and connective tissue; and four cartouches each containing 3.33 mg. of radium element, filtered through 0.5 mm. of platinum and 1.5 mm. of gold, are inserted (enclosed in a 3 mm. rubber tube of which the anterior end is placed between the scalene muscles and the posterior beneath the omohyoid). At the completion of the radical operation two rubber tubes, each containing half as much radium again as that in the supraclavicular tube, are left in—one hollow the clavicle parallel to the vessels, and the other along the serratus magnus at the border of the latissimus dorsi. The tubes are drawn out by attached threads after fifty hours. Post-operative x-ray applications are made twenty to twenty-eight days later. This technique is designed to expose to cross-fire radiation the axillary and subscapular fossae and the retroclavicular communications between the gland, above and below the clavicle—the two regions of the centripetal lymph flow which experience has shown to be most frequently the site of recurrences. Healing of the wounds has been little retarded, and the immediate operative results were satisfactory. The author agrees that it is too early to estimate the final results.

#### 71. Tubal Rupture.

H. O. NEUMANN (*Zentralbl. f. Gynäk.*, October 25th, 1924, p. 2378) questions the accuracy of exploratory puncture in diagnosing tubal rupture. Owing to the difficulties of diagnosis in these cases puncture through the posterior vaginal fornix has come to be trusted for the provision of final proof. The author quotes a case of a multipara in whom haemorrhage accompanied many of the early symptoms of pregnancy. By vaginal examination the uterus was found to be enlarged and a soft swelling was detected near the left ovary. A leucocytosis of 36,000 per cubic millimetre was present. By an exploratory puncture dark altered fluid blood was obtained, and as this seemed to clinch the diagnosis laparotomy was performed. No free blood was found in the abdomen, and the tubes were not inflamed, but the uterus was slightly enlarged, and posterior to it there was a retroperitoneal haematoma. The author refers to two cases of tubal rupture in which exploratory puncture produced clear fluid. He concludes, therefore, that the test is not infallible, and does not always provide the conclusive proof desired.

## Pathology.

#### 72. Fermentative Reactions of the Diphtheria Bacillus.

C. C. O'KELL and E. M. BAXTER (*Journ. Path. and Bact.*, October, 1924, p. 439) have carried out an extensive investigation on the fermentative properties of the diphtheria bacillus. The cultures chosen for examination numbered 430, of which 200 were virulent to the guinea-pig and 230 avirulent. All were derived from the throat, nose, or ear of cases of diphtheria or of carriers. The medium used was nutrient broth, containing 1.5 per cent. of peptone, to which the sugars to be tested were added in a proportion of 0.5 or 1 per cent. The nutrient broth basis was made up in double strength; the sugars were dissolved in distilled water, filtered through a Pasteur-Chamberland filter, and added in equal quantity to the broth. The tubes, after inoculation, were examined on the first, fifth, and tenth days of growth at 37° C., and sometimes after fourteen and twenty-one days. All cultures used were derived from single colonies, obtained by plating, often repeatedly. The results were surprisingly consistent. The 200 virulent strains without exception fermented glucose with the production of acid, and failed to ferment sucrose. Of the 230 avirulent strains 200 fermented glucose but not sucrose, 4 belonged to the Hoffmann group, fermenting neither sugar, and 26 belonged to the *aerosis* group, fermenting both sugars. From these results they consider it justifiable to define the avirulent *B. diphtheriae* as an organism morphologically virulent *B. diphtheriae* which ferment sucrose, and which produce toxin either *in vivo* or *in vitro*.

This point was settled they proceeded to an examination of other sugars, using a rather smaller number of strains. They found that maltose, galactose, dextrin, and laevulose were fermented, and that lactose and salicin were never only slightly. Glycerol was likewise fermented, though often as the virulent strains gave the same reactions as the avirulent strains, except that they occasionally failed to ferment dextrin. For practical purposes they conclude that

the only sugars which are of real value in differentiating the diphtheria from the diphtheroid bacilli are glucose and sucrose. The fermentation of the former and the non-fermentation of the latter is absolutely constant for both the virulent and the avirulent diphtheria bacilli, as is shown by repeated tests of the same organisms at intervals of several months.

#### 73. The Blood Picture in Post-operative Tetany.

A. SCHLOSSER (*Zentralbl. f. Chir.*, November 8th, 1924, p. 2476) remarks how little attention has been paid to the blood picture in totany following injury to or removal of the parathyroids. Haas alone reports a case of post-operative totany in which there was a fall of the polymorphonuclear leucocytes from 75 to 60 per cent. in six days with a rise of the lymphocytes to 31 per cent. and of the eosinophils to 5 per cent. How far the administration of parathyroid tablets was responsible for this change could not be determined. Haas, however, concluded that post-operative tetany has a considerable effect upon the blood-forming organs. Schlosser has recently had the opportunity of studying the blood picture in two cases of totany which developed five days after thyroidectomy. In one case transplantation of the parathyroid was performed under the rectus abdominis, but without having any effect on the tetany. In neither case was there any characteristic change in the blood picture, either during the attack of tetany or in the intervals between the attacks.

#### 74. The Influence of Fats on Tar Cancer in the Mouse.

J. LECLOUX (*C. R. Soc. de Biologie*, November 28th, 1924, p. 1155) reports some experiments dealing with the influence of fats on the development of tar cancer in the mouse. Other workers had succeeded in rendering the mouse refractory to cancer grafts by injections of unsaturated fatty acids; in rabbits the effect appeared to be different, the animals becoming more susceptible. In the present experiments 8 control mice were treated by rubbing the skin with tar every four days; in all, forty mice were made during a period of 5 of the mice before the 135th day, and all the mice had developed definite cancerous tumours by the 200th day. These tumours were very large; some were accompanied by lymphatic and pulmonary metastases, and in all cases they were preceded in their development by papillomata. By the 255th day 6 out of the 8 mice were dead. At the same time as those controls 9 experimental mice were treated with tar in the same way, but in addition they were rubbed with a 20 per cent. solution of sodium oleate, which was applied to the same area as that to which the tar had been applied; the injections were interpolated between those of the tar. The first mouse to develop a papilloma showed a lesion on the 166th day, at a time when 7 of the control series were affected. Not till the 255th day, when 6 of the control mice were dead, had cancer appeared in all the animals. Subsequently 4 of the mice died, but none of them had such extensive tumours as had the control animals. The two points emphasized are the delay in the appearance of the papillomata in the experimental series—a delay of thirty to fifty days—and the smaller size to which they attained. The author considers that the active radical in the sodium oleate is the oleic fraction, not the metallic ion. Whether it acts upon the general system or whether its action is local, confined to the area in which the cancer is formed, he is unable to say; experiments are in progress with a view to solving this point.

#### 75. A New Method of Staining Spirochaetes.

J. SCHUMACHER (*Dermatol. Woch.*, November 22nd, 1924, p. 1514) refers to Mühlfordt's experiments with "Victoria blue" as a stain for *B. leprae*; he states that this stain has a definite affinity for lipoids and that it is now recognized that spirochaetes have lipid envelopes. Schumacher has modified Mühlfordt's original formula, and now uses a stock solution, prepared as follows: Victoria blue (2 parts) dissolved in 50 per cent. absolute alcohol, mixed with an equal quantity of 4 per cent. aqueous solution of carbollic acid, to this being added a 10 per cent. aqueous solution of glycerin. Though exposed to diffuse sunlight, such a solution has remained quite active and free from precipitate for more than two and a half years. Schumacher's method is as follows: the smear containing spirochaetes is fixed with alcohol; the Victoria blue solution is then poured over the slide and is heated for fifteen seconds, as when staining tubercle bacilli by the Ziehl-Neelsen method. The preparation may be heated more slowly for thirty seconds, or it may be stained by immersion in the cold solution for three minutes.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 76. Organic Disease prolonged by Morphineism.

P. SOLLIER and D. MORAT (*Presse Méd.*, November 29th, 1924, p. 948) advocate rapid deprivation of heroin or morphine in cases in which the drug was prescribed originally for pain due to chronic organic disease. In their experience it happens very often that the original disease for which morphine was being prescribed clears up and the patient's health becomes very much better. The authors give a list of most diverse diseases cured or greatly relieved by deprivation of the drug. Their theory is that recovery from chronic organic disease is often prevented by the fact that the tissues of the body contain so much morphine that protoplasmic activity is inhibited to a great extent. They cite four cases. (1) A surgeon contracted septicaemia during an operation and eventually became a helpless invalid. Many deeply seated abscesses were opened, and chronic septic osteitis of the lower dorsal vertebrae developed, two fistulae discharging pus freely. Heroin had been prescribed for relief of pain, and the patient was receiving daily 1 gram of heroin hypodermically. When the injections were discontinued there was a definite increase of pus which continued for nearly four weeks. The patient's general health improved greatly, and later only a slight scrous discharge remained. Then a sudden lighting up of the inflammation occurred, abundant discharge of pus returned, and a sequestrum—a portion of a splinous process—presented at one of the fistulae. After its removal recovery was rapid and uninterrupted, and the patient returned to his practice. (2) A physician had resorted to heroin for the relief of the intolerable pain and discomfort due to dermatitis herpeticiformis, which had been treated for more than two years by many French and German specialists. He was emaciated and almost cachectic. During the fifteen days in which the daily dose of heroin was reduced and finally stopped, retention of urine required repeated catheterization; but there was a progressive improvement in the skin condition in spite of relapses accompanied by the appearance of eosinophilia in the blood and also in the serum of the vesicles. Radiotherapy of the spleen and vertebrae accelerated his recovery, which was eventually complete. (3) A patient with psoriasis who was taking by the mouth 0.6 to 0.8 gram of heroin daily was cured by deprivation of morphine. (4) A married woman had chronic peritonitis after her second confinement. She developed large doughy masses in the abdomen which were believed to be tuberculous, and became a helpless invalid. Morphine and heroin had been prescribed and injected regularly for several years. Spahlinger's serum and sanatorium treatment gave no relief, but she made a rapid recovery when heroin and morphine were discontinued.

### 77. The Gastric Juice in Old Age.

L. DEDICHER (*Acta Med. Scand.*, Supplement VII, 1924, p. 345) has investigated the acidity of the gastric juice of 110 elderly people, in apparently good health, in an infirmary in Oslo (Christiania). Out of 102 persons, whose ages were between 67 and 92, 3 had cancer of the stomach, and were therefore not suitable for this investigation. There remained 99, of whom only 36 were men. Absence of acidity was found in 66, being demonstrable in 80 per cent. of the men and 53.7 per cent. of the women. By classifying these persons in age groups it was found that the frequency of the absence of acidity increased with age. As many as 76 showed signs of gastritis due to diminution or absence of acidity, indicated by the amount of mucus in the stomach and other evidence. Only 14 of these suffered from mild dyspepsia; the others had good appetites and tolerated their food well. Most of these 93 persons were entirely toothless. An investigation of the haemoglobin of 94 cases, in 63 of which there was no gastric acidity, frequently showed a mild degree of anaemia, as many as 26 having a haemoglobin percentage between 60 and 80. This anaemia was slightly more common in the abnormal cases than in those with normal acidity of the gastric juice. In 24 cases the number of the erythrocytes was between 2.9 and 4 millions. The author concludes that deficient acidity of the gastric juice is very common in old persons, is dependent on a mild gastritis, is usually without symptoms, and is probably caused by a combination of exogenous factors. In several cases of this condition in the aged the blood picture somewhat resembles that of pernicious anaemia, and is associated with urobilinuria.

### Meningitis in Varicella.

G. DE TONI (*Il Policlinico*, Sez. Prat., November 3rd, 1924, p. 1434) records the case of a girl, aged 3, who in the desclatous stage of varicella developed convergent strabismus, slight nuchal rigidity, Brudzinski's two signs, Babinski's sign on the left side, and marked cutaneous hyperaesthesia. The cerebro-spinal fluid escaped under pressure; it was xanthochromic, and not quite clear. The cells numbered 78 per cubic millimetre; 56 per cent. were lymphocytes, 14 per cent. polymorphs, and 30 per cent. ependymal cells. The albumin was 0.58 per cent. There was a slight deficiency of sugar in the cerebro-spinal fluid. The Pandy, Boveri, Nonne-Apert, and Welschbrodt reactions in the fluid were positive, and the Wassermann reaction . . . . . bacilli were found in the deposit, . . . . . the guinea-pig inoculation tests were . . . . . of the ears, blood, and urine was also negative. A provisional diagnosis of tuberculous meningitis was made, but apart from left internal and external ophthalmoplegia complete recovery took place. In the absence of any other cause, de Toni regarded varicella as responsible for the meningitis in this case. Only four other examples of meningitis due to varicella are on record, reported by Myn, Koplik (two cases), and Lenoble and Thielement respectively. Koplik's patients recovered, while the others died.

### A New Vascular Sign of Death.

M. H. KAHN (*Amer. Journ. Med. Sci.*, December, 1924, p. 890) describes certain changes in the appearance of the small blood vessels, especially the veins, throughout the body at death; transverse interruptions occur in the red colour of the vessels, giving an appearance of division or striction of the blood column. He finds that these changes are best seen in the fundus of the eye. They are accentuated by pressure upon the eyeball, the interruptions becoming altered in size up to the first three hours after death, after which manipulation and pressure fails to have any effect. At death the blood flow in the smaller vessels and capillaries ceases, clumping of the corpuscles occurs, and a forward movement commences in the capillaries and slowly proceeds towards the larger vessels. The degree of emptying of the vessels varies in different cases. Kahn states that this segmentation of the venules and arterioles has not hitherto been described, but he maintains that it is a definite sign which should rank with the other clinical signs of death.

### Statistics of Cholelithiasis.

T. W. TALLQVIST (*Finska Läkarsällskapets Handlingar*, September-October, 1924, p. 759) has investigated 206 cases of gall stones in which the duration of the disease was one to thirty years. In 110 cases information was obtained about the patient's subsequent fate. It was found that the average age at the onset of symptoms was 44 for women and 49 for men. Still greater differences between the age incidence at onset of disease in men and women were found when the women and men were grouped in decades: the age of greatest frequency for women was between 30 and 40, while the highest incidence for men was two decades later. About 66 per cent. of all the patients complained of dyspeptic disturbances, and of the 116 whose gastric juice was analysed 59.2 per cent. showed achylia or marked hypochylia, 3 per cent. heterochylia, 28.5 per cent. normal secretion, and 9.3 per cent. hyperacidity, which was not, as a rule, marked. Only in 2 cases was there evidence of gastric or duodenal ulcer. With regard to the expectation of life, it was found that 17 of the 110 patients who could be traced were dead. The comparatively high death rate among the men should be associated with the fact that they were, on the average, much older when the disease began. Only 9 of the 17 deaths were caused by the gall stones, and thus the mortality directly due to gall stones may be put at 8 per cent. In about 14 per cent. of all the cases the author found evidence of anomalous conditions of the endocrine system.

### 81. Spirochaetosis Icterohaemorrhagica and Bathing.

G. RAILLIET (*Bull. et mém. soc. méd. hôp. de Paris*, November 13th, 1924, p. 1502) records a case which he had seen in August, 1923, of severe jaundice accompanied by haemorrhages and anaemia, which ended fatally on the tenth day, in a man, aged 30, in whom the disease set in directly after a water polo match. The diagnosis of spirochaetosis icterohaemorrhagica was made, although the serum test could not be performed. During the same month Railliet saw four cases of less severe icterohaemorrhagic spirochaetosis, all of

which occurred in the course of ten days among young persons aged from 19 to 32 who had been enthusiastic bathers in the river Vesle. Examination of the mud and water by Auguste Petit showed a spirochaeta morphologically resembling *Spirochaeta icterohaemorrhagiae*, but without any pathogenic action on guinea-pigs, so that the etiology of the outbreak could not be determined. About six weeks later an epidemic of mild catarrhal jaundice broke out in the valleys of the Vesle, Aisne, and Marne, and lasted from October, 1923, to February, 1924. The serum tests on this occasion were positive. M. GARNIER (*ibid.*, November 27th, p. 1591), commenting on Raillet's paper, alludes to similar cases in the literature. In addition to the examples of infective jaundice recorded by Keisch and attributed by him to baths taken in rivers with polluted water, as in the epidemic of Magdeburg in 1874, Uffenhuth and Fromme had more recently incriminated swimming baths in the etiology of spirochaetosis icterohaemorrhagica; and Garnier himself and Relifly had found that many of the patients with spirochaetosis icterohaemorrhagica in the Paris hospitals had taken a bath in the Seine eight to ten days before the appearance of their symptoms. Examination of Seine water, however, 700 c.cm. of which was centrifugized and the clot injected into guinea-pigs, was negative. As regards the relation of spirochaetosis icterohaemorrhagica with catarrhal jaundice, Garnier adds that during an epidemic of spirochaetosis some cases might not differ clinically in any respect from ordinary catarrhal jaundice, but he does not think that an epidemic of spirochaetosis has been recorded in which all the cases presented the appearances of ordinary catarrhal jaundice. In some cases at least the disease assumed the ordinary type of infective jaundice with febrile relapses.

## 82. Etiology of the Stokes-Adams Syndrome.

G. BICKEL (*Arch. des Mal. du Cœur, des Vaisseaux et du Sang*, December, 1924, p. 744) agrees with Lian that a permanently slow pulse, not associated with the Stokes-Adams syndrome, indicates syphilis as the cause. Permanent bradycardia is one of that important group of endo-vascular diseases which has recently been attributed to syphilis; the others are aortic aneurysm, aortic regurgitation, and angina pectoris. There can be no question regarding the syphilitic etiology of the two former, but the relation of angina pectoris to syphilis is not so certain. Gallavardin has shown that two-thirds of his cases of angina pectoris are non-specific. Bickel claims that the question of the syphilitic origin of the Stokes-Adams syndrome also requires revision. Gallavardin (1910) wrote that "the time is not far distant when nearly half of the cases of the Stokes-Adams syndrome will be recognized as of syphilitic origin." That opinion has been confirmed by reports of some cases of permanently slow pulse cured by antisyphilitic treatment. Evoli (1922) stated that syphilis should be suspected in the great majority of cases, even in the absence of a syphilitic history and a positive Wassermann reaction. Bickel has collected seven cases of typical Stokes-Adams syndrome, admitted to the Medical Clinic, Geneva, between 1917 and 1924. Only one of these patients had a positive Wassermann reaction, but, with the exception of the lesion of the bundle of His, there was no personal or familial evidence of syphilis. The other six patients had negative Wassermann reactions and no sign of syphilis. In two cases, autopsy revealed advanced cardiac atheroma with calcareous plaques in the membranous septum and invasion of the bundle of His. In the third case, there was very advanced coronary arterio-sclerosis, which had obliterated some of the branches, with consequent necrosis of the adjacent bundle of His.

82. suffered from generalized of the valves, and the other from obesity with advanced cardiac hypertrophy and myocardial degeneration. Bickel claims that these observations suffice to show that syphilis is a far less important agent in the etiology of the Stokes-Adams syndrome than has been supposed. He adds that it has been forgotten that the usual lesions of arterio-sclerosis and of atheroma are much more common than are syphilitic lesions in the neighbourhood of the bundle of His. Goodall (1920) has recorded twenty cases of total heart-block, in only one of which was there a history of syphilis and a positive Wassermann reaction.

## Surgery.

### 83. Pruritus Ani.

J. F. MONTAGUE (*Journ. Amer. Med. Assoc.*, November 29th, 1924, p. 1747) argues that the itching of pruritus ani signifies the existence of disease, just as does pain of any kind. Although purely palliative treatment of pain is unscientific, and therefore generally condemned, yet too often local treatment of pruritus is undertaken without

search being made for the underlying cause. Chronic visceral disease is often found associated with a local pruritus, and the author suggests, with the aid of diagrams, that the itching is due to a transference of afferent sensory impulses from the diseased viscera through the posterior spinal ganglia and spinal cord to the somatic afferent nerves. Pruritus is therefore to be considered a possible symptom of visceral disease, and in all cases pelvic and abdominal examination should be made. Carcinoma of the sigmoid and rectum should be especially borne in mind. The author describes cases in his own practice where this symptom led to the detection of visceral disease, the removal of which cured the pruritus, no local treatment being necessary.

### 84. Surgical Treatment of Obstinate Pruritus Ani.

L. FRANKENTHAL (*Zentralbl. f. Chir.*, November 8th, 1924, p. 2484) states that the operation for idiopathic pruritus ani should consist of three parts, the first being excision of the affected skin area, the second nerve resection or neurectomy, and the third plastic repair of the skin defect. He records an illustrative case in a man, aged 27, whose pruritus originated from an attack of pediculosis during the war; it had since resisted every form of medical treatment, including the application of x rays, so that he threatened to commit suicide unless he could obtain relief. The perineum showed a thickened, pigmented, and excoriated area of skin measuring  $4\frac{1}{2}$  by  $1\frac{1}{2}$  inches, extending from the anal mucous membrane forward over the root of the scrotum for three fingerbreadths. The sphincter was dilated under general anaesthesia, the affected skin area excised, and the pudendal nerve dissected out to its exit from the ischio-rectal fossa. On one side the perineal nerve was completely resected, while on the other it was retained, especially the branch to the labius urethrae. The fine branches, including the posterior scrotal nerves, were removed on both sides, while the vessels were preserved. Recovery was uneventful. After the operation the patient felt no more pruritus and became sound in mind. Histological examination of the excised piece of skin showed the changes characteristic of chronic eczema, but the excised nerves did not present any special lesions.

### 85. Tetanus Originating from a Gastric Ulcer.

P. SCHMUZIGER (*Deut. Zeit. f. Chir.*, Bd. 188, November, 1924, p. 161) states that though any injury to the surface of the body as well as damage to the buccal mucosa or a carious tooth may serve as an entrance for tetanus infection, only a few cases have been recorded in which the infection originated from a varicose ulcer. Andrews and Horder recorded in 1917 an example of this kind with recovery, but since that date Schmuiziger has been unable to find any further instances in the literature. He now reports a case which he had observed at the Zürich Surgical Clinic in a woman with a varicose ulcer in the middle of her right calf the size of a 5-franc piece. The duration of the incubation period and the source of infection could not be determined, but the incubation period was probably short, as is the rule in severe cases. In spite of serum, chloral, and morphine the attacks increased in number and extent, and the temperature, which was  $101.2^{\circ}$  on admission, rose to  $107.6^{\circ}$  on the following day three-quarters of an hour before death, which took place after a spasm of the diaphragm. Four white mice which were inoculated with material from the ulcer on the patient's admission died of tetanus in eighteen hours. The ulcer was then swabbed vigorously with iodine and some more mice inoculated, which did not succumb until twenty-four hours later.

### 86. Non-perforating Gastric and Duodenal Ulcers.

J. E. BRIGGS (*Boston Med. and Surg. Journ.*, December 11th, 1924, p. 1101), from a series of 38 cases (12 gastric and 26 duodenal) of non-perforating ulcers treated by surgical operations, points out the frequent association of carious and defective teeth with infections of the alimentary tract, and urges that special attention should be paid to cleansing the teeth and mouth several days prior to operation. Such symptoms as epigastric pain, loss of weight, vomiting, pyrexia, and haemorrhage are, he finds, the most constant in order of frequency; the clinical history and x-ray examination are the main diagnostic factors; duodenal ulcers occurring twice as often as the gastric kind. He believes that acute ulcers should be treated medically, and chronic indurating ulcers surgically; the ideal operation is gastro-enterostomy with excision of the ulcer in gastric cases, and destruction with the cauter in duodenal cases, especially when haemorrhage has occurred, and in order to obtain a radical cure. The early post-operative vomiting, indicative of dilatation of the stomach, should be treated by gastric lavage; if protracted, it points to the existence of intestinal obstruction necessitating further operation. He advises that during the operation the gall bladder and

appendix should be systematically examined; they should be removed if found to be diseased unless this step is contra-indicated. He concludes by pleading for re-examination of these patients three months after operation in order to obtain more full and accurate knowledge about their ultimate condition.

#### 87. Septic Meningitis.

W. E. DANDY (*Surg., Gynecol. and Obstet.*, December, 1924, p. 761) points out that the operative treatment of septic meningitis has gained little favour with the passing years. Despite the fact that the operative possibilities almost seem to have been exhausted, no impression has been made on the high mortality of the disease. Three types of treatment have been tried—repeated lumbar puncture, continuous drainage, and irrigations of the subarachnoid space. None of these methods has demonstrated any outstanding superiority over the results obtained when the case is untreated. Dandy advocates early continuous drainage of the cisterna magna in the treatment of meningitis in which the infecting organism is the staphylococcus or streptococcus. Three out of four cases so treated survived. This method is not urged in other cases as it is felt that the character of the would probably make drainage laceration is made over the occiput and a circular area of bone removed. The dura is opened and a small catheter fixed into the cisterna magna. Drainage is remarkably effective, and no noticeable effect followed the continuous loss of cerebro-spinal fluid. The author points out that drainage alone cannot cure meningitis; the body must also be able to combat the infection. It is not to be expected, therefore, that any operative method will do more than reduce the present high mortality rate.

#### 88. Death following Gastroscopy.

F. SAUERBRUCH (*Zentralbl. f. Chir.*, September 20th, 1924, p. 2071), who records an illustrative case, states that it is not the only example of the kind, as several fatalities following gastroscopy have been reported by Schindler and Sternberg. Gastroscopy, therefore, should not be regarded as a harmless procedure, since it is decidedly more dangerous than exploratory laparotomy. In Sauerbruch's case the gastroscopy was undertaken by Sternberg with the patient in the knee-elbow

patient developed symptoms of severe mediastinitis, for which Sauerbruch had to expose the oesophagus and drain the mediastinal cavity. Intense purulent retro-oesophageal cellulitis was found extending from the level of the pharynx to the mediastinum. After slight improvement the patient died the following day. The autopsy showed that the musculature in a circumscribed area in the upper segment of the oesophagus was lacerated, while the mucous membrane was intact. The tonsils also showed some ecchymoses which had been caused by introduction of the gastroscopy tube.

#### 89. Staphylococcal Septicaemia.

A. MOYA (*Arch. de med., cir. y esp.*, November 22nd, 1924, p. 349) states that in view of the rarity of staphylococcal septicaemia the following case justifies publication. The patient was a man, aged 25, in whom high fever and a typhoid state at first suggested typhoid fever, but this diagnosis was excluded by the rapid pulse, absence of abdominal symptoms and rose spots, an area of lymphangitis on the inner side of the left thigh, and a leucocytosis of 24,000 cells, of which 79 per cent. were polymorphonuclears, 17 per cent. lymphocytes, 2 per cent. large mononuclears, and 2 per cent. transitional cells. The probability of streptococcal septicaemia was considered, especially as streptococci were cultivated from an abrasion on the leg from which the lymphangitis originated. Blood cultures, however, which were at first negative, yielded a pure growth of *Staphylococcus pyogenes aureus*. In spite of injections of sensitized anti-staphylococcal vaccine the temperature remained high and irregular, and the wound became gangrenous. Death took place before amputation could be performed. The autopsy confirmed the diagnosis by showing the slight degree of local and general changes characteristic of every form of septicaemia. No metastatic foci were present. The most interesting feature of the case was the fact that an apparently insignificant portal of entry should have admitted a fatal septicaemia. At the present time most bacteriologists, following Jochmann, Schottmüller, and others, hold, in opposition to Wassermann and Kollo, that septicaemia does not arise by multiplication of the organisms in the blood, but by continual passage of the organisms into the circulation from the original locus, which may be the wound itself or, much more frequently, the inflamed veins or lymphatics in the neighbourhood of the wound.

#### 90.

#### Melanoma of the Nail-bed.

T. B. JONES (*Annals of Surgery*, December, 1924, p. 839), in discussing melanoma of the nail-bed, remarks that this condition has been called "melanotic whitlow" because of its resemblance to a whitlow. In many of these cases trauma of the nail antedates the subsequent development of the lesion. It is, however, doubtful whether this is a coincidence or a stimulus to growth of a pre-existing lesion. The disease develops usually in persons over 50 years of age. Clinically at first it resembles a small haematoma beneath the nail, and the lesion appears as a paronychia, which gradually increases in size, ulcerates, and destroys the nail. Small areas of black pigment are seen to be scattered through the lesion. It progresses rapidly, extensive metastases occurring throughout the body. The chief difficulty in these cases is early diagnosis, to which the presence of black specks or a black border to the initial lesion is usually the key. In some cases, however, no pigment may show till relatively late in the disease. Chronic ulcerative lesions in the nail-bed of elderly persons which do not respond to treatment should always be regarded with suspicion; in such cases excision and microscopical examination of a small piece of tissue is indicated. The treatment advised is amputation of the digit and complete resection of the regional glands as a minimum; x-rays and radium appear to be ineffective. The prognosis depends on early diagnosis; it is usually very poor when the lesion is finally recognized, and hopeless when metastases have occurred. Three cases are described by the author, all of which were hopeless owing to general metastases.

#### 91.

#### Etiology of Cancer of the Oesophagus.

W. FISCHER (*Klin. Woch.*, December 9th, 1924, p. 2288) considers the statements which have been made respecting the frequency of cancer of the oesophagus amongst the Chinese, and the view that it is due to the eating of hot rice. This view he rejects. He then considers what little is known respecting the etiology of cancer of the oesophagus, and points out that there are many facts in favour of the view that it is excited by chronic irritation. The disease occasionally develops in an old stricture due to injury by the oesophageal sound, or following the pressure of an aneurysm, or an exostosis from the body of a vertebra. He adds that cancer is most liable to develop at the three points where the oesophagus is narrowest. The disease is much more common in men than in women. The influence of alcoholic excess has been much disputed. In Argentina the disease has been regarded as the result of drinking very hot "maté"; in China the drinking of hot arrack has been regarded as an exciting cause. The author thinks that alcoholism is a possible exciting cause; and in hot arrack and hot "maté" both chemical and thermal irritation may act as exciting factors. Other factors, as regards diet and other irritation, possibly play an important part in the etiology.

## Therapeutics.

#### 92. Desiccated Red Bone Marrow in the Treatment of Anaemia.

W. THALHIMER (*Journ. Lab. and Clin. Med.*, November, 1924, p. 129) has confirmed the investigations of Leake, who found that desiccated red bone marrow and spleen, combined in equal proportions by weight, caused a rapid and marked increase in the number of circulating red cells, with a rather less marked increase in haemoglobin. Thalhimier has administered this remedy in three daily doses, each of 5 grains, to forty-six patients with anaemia secondary to such conditions as tuberclosis, haemorrhage, pleurisy, and cardiac disease. He considers the good response of the patients with pulmonary tuberculosis to be of considerable interest, but in four patients with pernicious anaemia a fall in haemoglobin and the red cell count resulted. Out of his forty-six patients with secondary anaemia forty-one showed a very definite improvement. He believes that this treatment requires to be continued for six or eight weeks in order for the benefit to be permanent.

#### 93.

#### Mercurochrome Treatment of Erysipelas.

J. A. JACKSON and C. L. JOHNSTON (*Therapeutic Gazette*, December 15th, 1924, p. 843) have investigated the use of mercurochrome in the treatment of erysipelas. Intravenous injections of a 1 per cent. solution of mercurochrome in freshly distilled water were given, the doses ranging from 20 to 40 c.cm., according to the weight of the patient; twenty-four hours later a second dose was usually given. In most cases a sharp rise of the temperature curve was noticed, followed by a fall. In all primary cases of erysipelas there was a secondary rise, but rarely so high as the initial rise.

In recurring cases the temperature in every case fell to the normal after the initial rise, and there was no secondary rise. In most cases the local inflammation became less and its extension was stopped, this being more especially marked in the recurring cases. Untoward symptoms reported were diarrhoea and stomatitis, the first occurring in all cases except two. In one case there was severe haemorrhage from the bowel four days after the injection of mercurochrome. Stomatitis was noted in three out of seventeen cases, one case being very severe. Two patients died, and the autopsy brought to light pronounced inflammatory changes in the kidneys. The authors conclude that in mercurochrome may be used with advantage in selected able-bodied patients who have no kidney involvement, in recurring cases, and in severe cases with blebs and vesicles. They suggest that a kidney function test should precede its administration. Clinical details of the seventeen cases treated are supplied.

94.

## Treatment of Tetanus.

G. SMITH and W. E. LEIGHTON (*Amer. Journ. Med. Sci.*, December, 1924, p. 852) discuss the treatment of tetanus, with special reference to the use of magnesium sulphate. Administered in a sterilized 25 per cent. solution either subcutaneously, intramuscularly, intraspinally, or in a 6 per cent. solution intravenously, its action is sedative, controlling the spasms, and preventing death from exhaustion or asphyxia, thus assisting the patient to eliminate the toxin. The only serious danger reported is the possibility of respiratory effect can be relieved by calcium this respiratory action. A 2.5 per cent. calcium chloride in normal saline given slowly intravenously in severe cases usually restores the spasms within thirty seconds, but in less severe conditions 10 to 15 c.cm. of a 2.5 per cent. solution given intramuscularly more gradually neutralizes the unfavourable effect without causing a recurrence of the tetanic spasms. As a routine method prophylactic antitoxin subcutaneously is advised in all suspicious cases. During a tetanic attack it should be given intravenously, or intraspinally in severe cases, the spasms being controlled by the subcutaneous injection of magnesium sulphate, with recourse to the intraspinal or intravenous route if urgent symptoms arise, and the addition of morphine injections if necessary. The infected wound should be opened and treated with tincture of iodine, serum being injected locally. Fluids, nourishment, and careful nursing are essential, and an intramuscular or subcutaneous injection of serum should be given on the eighth or ninth day to maintain prophylaxis. The two authors contribute details of several cases in which this treatment was employed, and a bibliography of fifty-nine references is appended.

## 95. Another Arsenical Spirochaeticide and Trypanocide.

A. ALBERT (*Klin. Woch.*, November 25th, 1924, p. 2184) considers it improbable that further progress in reducing the toxicity of the salvarsan group will be made. Ehrlich himself recognized that although in the majority of cases the fullest therapeutic effect could be attained by means of the arsenobenzol series, their unstable composition must always render them dangerous in certain cases. In spite of all precautions, and of every improvement in technique, the presence of a small excess of  $\text{CO}_2$  or of oxydases in the blood, may when  $\text{CO}_2$  or oxydation products in the tissues are in contact with the arsenobenzol molecule. The critical point in the theory of the chemical action of the salvarsan group is that the hydroxyl groups of the arsenobenzol molecule—the hydroxyl and amido groups—may be the active agents in the production of arsenic activity. This suggests that the phenol-hydroxyl, the carboxylic and salicylic acid, and the N-basis quinolin groups, in conjunction with the arsenic molecule, may produce a series of compounds which will be as powerful as the salvarsan group in their action on protozoal parasites, but without the instability of the arsenobenzol series. Albert states that an oxydation product, which he terms "proxyphenylarsenoxide," is a powerful protozoal poison which is without the disadvantages and dangers of arsenobenzol. The aqueous solutions of this substance ("Albert 102") are alkaline in reaction and do not undergo oxydation. Albert adds that in the interest of the patent rights he refrains from giving the constitution formula.

95. F. KALBERLAH (*ibid.*, p. 2185) gives a brief outline of the experimental work carried out by Gail and himself with the new arsenical preparation "Albert 102." It was injected into 400 rabbits infected with experimental syphilis, rabbit spirochaetosis, or trypanosomiasis; it was also administered to more than 4,000 mice and rats infected with trypanosomiasis. "Albert 102" is an amorphous powder, faintly alkaline to phenolphthalein. It forms a colloidal solution in

water and, like salvarsan, is also soluble in glycerin, glycol, and other liquids. According to Kalberlah's tables it contains the same quantity of arsenic (20 per cent.) as neosalvarsan, as compared with the 34 per cent. of "old" salvarsan. The toleration dose employed in each case was much smaller than that of the arsenobenzols. According to Kalberlah the curative dose was also smaller than in the salvarsan group. The author has used "Albert 102" in nine cases of general paralysis. Of these three were not improved, two were much improved, one died "of a relapsing type of paralysis, such as we are familiar with in connexion with salvarsan." He has also treated eleven cases of tabes; ataxia and pain were much relieved after ten to fifteen injections. An old case of cerebral syphilis was greatly improved. In seven cases of multiple sclerosis four were much improved objectively and subjectively. Schuster (Budapest) has also reported a similar result in this disease.

97.

## The Physiology of Massage.

R. PEMBERTON, F. A. CAJORI, and O. Y. CROUTER (*Journ. Amer. Med. Assoc.*, November 29th, 1924, p. 1761) have investigated the influence of massage on the chemistry of the fixed and fluid tissues of the human body. Five patients suffering from arthritis were selected, and various estimations were made before and after massage treatment. It was found that massage, however rigorous, was not accompanied by the production of lactic acid and acidosis, differing thus substantially from voluntary exercise. There was also no evidence of loss of acid or alkalosis, as occurs when the body is exposed to heat. They consider, therefore, that the benefits of massage in arthritis must be derived from circulatory changes, and point to the existence in this disease of some circulatory defect, possibly in the capillary areas. They add that massage can be used as a partial substitute for active exercise in many conditions, but that its value depends on some mechanism other than that concerned in the production of chemical changes in the tissues.

## Anaesthetics.

## 98. Methylene Chloride as a General Anaesthetic.

MENSCH (*Deut. med. Woch.*, November 21st, 1924, p. 1607) gives an account of the anaesthesia induced in more than 500 cases at his hospital during the past year with methylene chloride prepared by the firm of Meister, Lucius, and Brinck, Höchst, and sold as "solisthlin." It is obtained by the purification of commercial dichloromethane, and it contains 1 per cent. of alcohol added as a preservative. It is a clear colourless fluid, smelling rather like chloroform. It is dropped slowly on to a folded piece of muslin or used with a Schimmelbusch mask, one or two drops being added every second. Only in two cases did the drug prove unsatisfactory; too much had been given and great excitement was provoked. The drug was not used to induce complete relaxation with anaesthesia, as in major operations, but only for the minor painful operations in the out-patient department, such as incisions, setting fractures, reducing dislocations, and making painful examinations. Pain was never felt while the patients were under the influence of the drug, and they usually recovered consciousness a few minutes after they ceased to inhale it; this recovery of consciousness took a little longer than in the case with ethyl chloride, but it was never sudden and frightening. Unpleasant after-effects were rare and transitory, and no ill effects of long duration were observed. The ages of the patients were from 1 to 70 years. The author concludes that this drug is more effective than ether and less dangerous than ethyl chloride; it is easy to administer, its dosage can be controlled without difficulty, it is comparatively cheap, and is not inflammable. It does not give rise to bronchitis, and such sequelae as vomiting and headache are rare. He believes that it may be administered for a long period with impunity, but no fixed opinion should, of course, be formed as to its value until it has been used in many thousands of cases.

99.

## Obstetrical Anaesthesia.

L. CLEISZ (*Presse Méd.*, December 17th, 1924, p. 1001) remarks that of the various means by which it has been sought to obtain obstetrical anaesthesia chloroform and ether are impracticable, sufficiently prolonged administration being impossible; nitrous oxide is dangerous, analgesics are ineffective, and scopalamine and morphine are both dangerous and ineffective. He advocates the use of diethylamid diethylallylisopropylbarbiturate (sommifène), which was first given intravenously during childbirth by R. Perlis and himself. The present paper is based on forty cases, in thirty-seven of which the pains of labour were completely

suppressed. The dose recommended is from 6 to 11 c.c.m. injected slowly; occasionally a second dose has been necessary. Coincident injections of morphine are not recommended, but in about half the cases pituitary extract was given, and appeared to accelerate parturition considerably. The suppression of pain was such as to suggest general anaesthesia rather than analgesia. A few drops of chloroform were given in almost every case with the sole object of producing muscular relaxation. There was no evidence that the injections led to increased foetal mortality, or to inattention of the foetus in the uterus or of the newly born infant. In multiparae the injections were given as soon as labour had commenced, as indicated by modification of the cervix; in primiparae after thinning of the cervix and with the commencement of dilatation. The patients slept for some hours after labour was ended.

#### 100. Sacral Anaesthesia in Rectal Operations.

L. E. MOON (*Amer. Jour. of Surg.*, November, 1924, p. 267) points out that in sacral anaesthesia the anaesthetic solution is injected into the space between the dura and the inner walls of the sacrum, the injection being made through the sacral hiatus. The anaesthetic penetrates and diffuses through the dorsal nerve sheaths, so producing a block anaesthesia in the five sacral nerves. He considers it the method of choice for rectal operations because convalescence is shortened, the post-operative complications are lessened, and the depth of anaesthesia makes the operation less difficult. Pain after the operation is diminished, and the absence of urinary trouble is very noticeable; it is seldom necessary to catheterize patients after operation. He adds that post-operative haemorrhage is reduced, since sacral anaesthesia produces better haemostasis during the operation. The chances of infection are materially decreased because there are no injection punctures in the perineal region. Moon thinks that with careful technique there should be few fatalities, whilst pneumonia, acute dilatation of the stomach, or acidosis will not occur; further, the sphincter muscle is completely relaxed, and the patient is usually unaware of the act of dilatation. He concludes that a 1 or 2 per cent. solution of novocain as the anaesthetic probably gives the most satisfactory results.

#### 101. Ethylene Anaesthesia.

H. O. OBERHELMAN and HATTIE A. DYNEWICZ (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 2012) discuss the metabolic changes associated with ethylene anaesthesia. Favourable reports on the use of ethylene-oxygen have been received from many anaesthetists, and in our issue of September 27th, 1924 (*Epitome*, para. 234), we referred to a report by J. S. Lindy based on the treatment of 2,000 patients. Oberhelman and Dynewicz examined twenty-four patients between the ages of 17 and 64, before and after ethylene-oxygen anaesthesia. The operations performed were for inguinal hernia, haemorrhoids, acute osteomyelitis. They found the decrease in alkali reserve were less with this anaesthetic than with ethylene, chloroform, or nitrous oxide. At no time in uncomplicated conditions did the blood sugar change or alkali reserve approach a dangerous level. Two patients were examined with reference to ethylene-ether anaesthesia, and the indications were that the metabolic changes were more marked than with ethylene-oxygen anaesthesia. No significant changes in the non-protein nitrogenous constituents of the blood were observed. The authors add that the changes in blood pressure produced by ethylene-oxygen anaesthesia resemble more closely those of normal sleep than was the case when ether, chloroform, or nitrous oxide was the anaesthetic used.

## Obstetrics and Gynaecology.

#### 102. Renal Tuberculosis during Pregnancy.

W. E. STEVENS (*Surg., Gynecol. and Obstet.*, December, 1924, p. 750) considers that many cases of renal tuberculosis during pregnancy escape detection because morbid urinary symptoms are then comparatively common and because no thorough examination of the urine is made. He records the case of a woman, aged 22, who complained of frequent micturition during the fifth month of gestation. Investigation showed that the urine from the left kidney was normal, but pus cells and tubercle bacilli were found in the urine coming from the imperfectly functioning right kidney. Operation was refused until after birth of the child, which died at 8 months of tuberculous meningitis. The mother was quite well twenty months after nephrectomy had been performed. Stevens considers that if the tuberculous infection affects one

kidney only, nephrectomy is advisable without delay, irrespective of the pregnancy. The extra strain thus placed on the sound organ is more than counterbalanced by the removal of the source of infection and irritation. Nephrectomy during pregnancy is comparatively well borne; in an analysis of 34 cases in which the renal lesion was non-tuberculous Stevens has found that only 2 patients died, and one suffered from a uraemic attack, whilst the pregnancy continued to term in half of the cases. Of 12 pregnant patients in whom, according to the literature, nephrectomy was performed for renal tuberculosis, all recovered; normal children were delivered at term in 6 cases. After operation tuberculin treatment is advocated; a second pregnancy is said to be permissible if the remaining kidney is functionally normal and free from tuberculosis after two or three years. In bilateral cases Stevens prefers tuberculin and general treatment to induction of abortion, which, at best, prolongs the mother's life for only a short period.

#### 103.

#### Puerperal Infection.

P. DELMAS (*Bull. Soc. d'Obstét. et de Gynéc. de Paris*, 1924, 9, p. 762) advocates local treatment of puerperal infection both by surgical methods and the application of vaccines. He argues that if signs of infection appear during the first week after delivery, it is as logical to empty the uterus as to open and drain an abscess in osteomyelitis. The operation should be done under spinal anaesthesia. Loose fragments of placental cotyledons can be removed with the finger; retained placental portions by the curette; remnants of the ovarian membranes by the blunt scraper. The three procedures have often to be combined. To minimize the risk of bacterial dissemination leucocompresses are placed on the hypogastrium and ergot is administered. Delmas thinks that it is no longer justifiable to attempt to destroy pathogenic micro-organisms left in the uterus either by applications of strong antiseptics or by intermittent injection of Dakin's solution. After simple uterine lavage with 1.8 per cent. magnesium chloride solution, a drainage tube wrapped in gauze moistened with polyvalent serum is left in the womb. Subsequently similar local applications are made of vaccines on the lines suggested by Besredka. Stock vaccines are used until the lochia have been investigated bacteriologically, and later an auto-vaccine, which Delmas thinks, is possibly more effective by reason rather of its freshness than its specificity. General treatment includes injections of hexamethylene tetramine, production of a fixation abscess, and protein therapy. Delmas adds that operative clearing of the uterus must never be repeated, but in certain cases, if the uterus is found to be empty, vaginal hysterectomy may be indicated.

#### 104. Expectant Treatment in Ectopic Gestation.

K. GENTSCH (*Zentralbl. f. Gynäk.*, November 1st, 1924, p. 2440) mentions the case of a 2-para, aged 34, in whom an ectopic pregnancy continued to term. A living child was delivered by abdominal section, and four years later Gentsch found him to be healthy and well developed, weighing 3 st. The mother was operated on for gall stones, and no trace was visible of adhesions resulting from the extrauterine pregnancy. The case is quoted as supporting the school of treatment which advocates that after the fifth month ectopic pregnancy with living foetus should be allowed to continue until near term. Expectant measures have been rejected on the grounds that the maternal life may be endangered by internal haemorrhage, and that the foetus, if alive, is likely to be weakly and to show malformations. Mallowsky, however, from an analysis of nearly 200 cases of extrauterine pregnancy with living foetus, concluded that to allow gestation to continue involved the mother in no special danger, and that the most favourable time for operation was the thirty-eighth week of pregnancy.

#### 105. Adenomyoma of the Recto-vaginal Septum.

L. HERLY (*Surg., Gynecol. and Obstet.*, November, 1924, p. 626) records the case of a woman, aged 28, who four years after a high forceps delivery suffered from dyspareunia and bleeding after coitus, followed by a brown intermenstrual vaginal discharge. Later there was much pelvic pain, aggravated by exertion or defaecation. A small tender nodule was found in the right portion of the upper end of the recto-vaginal septum; it had respected the rectal mucosa, but had ulcerated into the vaginal fornix as a series of papillomatous excrescences, blood-red in colour, and bleeding on palpation. Removal per vaginam under general anaesthesia could not be completed and led to considerable bleeding. Microscopical examination showed cystic spaces lined with cylindrical epithelium surrounded by lymphoid tissue and embedded in plain muscle and fibrous tissue. The pain was relieved and the nodules disappeared one month after hard tubes of radium emanation had been buried in the tumours. A few months later, the patient having become pregnant, the

nodules recurred in their old sites and the symptoms returned. After therapeutic induction of abortion the radium treatment was repeated and the symptoms and signs disappeared. Another pregnancy soon followed; the patient was delivered at term by Caesarean section, the growths having in the meantime again recurred. Three years later the patient was free from morbid symptoms, and the site of the adenomyomatous nodules was occupied by telangiectases. Several observers have reported that during pregnancy the cellular stroma around gland tissue in an adenomyoma may take on decidal changes.

## Pathology.

### 106. Sedimentation Test in Congenital Syphilis.

G. GJELBERG-HANSEN (*Ugeskrift for Læger*, December 18th, 1924, p. 1011) suggests that the Fåhræus test (the rate of sedimentation of the erythrocytes) may be of use in deciding whether or not an infant suffers from congenital syphilis at a time when the Wassermann reaction is still negative and there are no clinical manifestations of syphilis. He points out that in the healthy infant the rate of sedimentation differs considerably from that of adults. This rate is very slow at birth (blood taken from the umbilical cord), and during the first weeks of life it is more rapid, though still considerably slower than in the adult. It increases gradually till, at the age of 2 months, the adult rate is reached. From the age of 2 to 12 months this rate is much faster than in the adult, and during childhood there is a gradual change of this rate towards the normal for an adult. At the hospital to which the author is attached many infants remain under observation because their mothers were syphilitic; in these infants he has carried out a series of Fåhræus tests, which invariably showed that, when the infants were syphilitic, the rate of sedimentation was greater than normal. It gradually returned to normal under the influence of specific treatment. A male infant, the offspring of a mother with a positive Wassermann reaction and papules on the genitals, showed no signs of syphilis; the Wassermann reaction was negative, and a microscopic examination of the umbilical cord showed no abnormality. When a week old the infant's rate of sedimentation was normal. But when 2 weeks old an abnormally rapid rate of sedimentation was observed, although the Wassermann reaction was still negative. It was not till a fortnight later that the Wassermann reaction became positive and the infant developed a purulent coryza. The value of the Fåhræus test in eliminating the diagnosis of syphilis was demonstrated in another case. The infant's mother had been treated for syphilis some time before, but not during pregnancy. At the time of birth neither the mother nor the infant gave a positive Wassermann reaction. When the infant was 17 days old an extensive eruption appeared, and syphilis was suspected. The rate of sedimentation was normal, however, and the conclusion was drawn that the eruption was not syphilitic.

### 107. Thyroid Administration and the Arneth Count.

E. PONDER (*Quart. Journ. Exper. Physiol.*, October, 1924, p. 327) has investigated the effect of thyroid treatment on the Arneth count in rabbits, which is normally very similar to that in man. Lim, Sarkar, and Graham Brown had shown that thyroid extract stimulates the marrow to produce polymorphonuclear cells. Ponder reports that it caused a percentage increase of those cells with the simple type of nucleus, constituting thus a fall in the Arneth count. The normal condition returned when the treatment was discontinued. The rabbits lost weight while the test was in progress. Ponder deduces that thyroid injection will cause a fall in the opsonic index similarly, and proposes to consider this point more fully in a subsequent paper.

### 108. Immunity of the Yellow Races to Scarlet Fever.

C. ZOELLER (*C. R. Soc. de Biologie*, December 19th, 1924, p. 1315) records how frequently he has treated Annamese workmen for diphtheria and mumps, but has never yet seen a case of scarlet fever amongst them. He has performed the Dick intradermal test for scarlatina on 50 Annamese and 125 white subjects living in the same neighbourhood, with the result that whereas there were 38 positive reactions amongst the latter group, there was not a single definite reaction amongst the former. In 4 Annamese there was a very feeble reaction at the point of injection and tissue perceptible only on the surface, given by the white patients with definite infiltration. If the generally accepted interpretation

of the Dick test be correct, then it must be concluded that the yellow races are much more resistant to scarlet fever than the white races. Zoeller asks if this immunity depends on the presence of antitoxin in the blood, or is some other factor responsible for it? To determine this point he examined the blood serum of 10 Annamese, mixing it with a streptococcal toxin, and injecting the mixture into the skin of a susceptible person. In 4 of the mixtures positive reactions were obtained; in 4 a pseudo-reaction—a slight reaction not appearing till two days after the injection—and with the remaining 2 no reaction at all. From these results he deduces that the immunity in the case of some subjects may rest on the existence of antitoxin in the blood, but that in others it must depend on some other factor, such as an insusceptibility of the tissues to the scarlatinal toxin, or on some local process of defence. Zoeller adds that the Dick test indicates that the threshold of immunity to scarlet fever is higher in the yellow than in the white races.

### 109. Kolmer Complement Fixation Test for Syphilis.

J. A. KOLMER and E. STEINFELD (*Journ. of Lab. and Clin. Med.*, October, 1924, p. 1) claim that this new method when properly conducted possesses three outstanding properties—namely, a very high degree of specific sensitiveness, an almost complete absence of non-specific reactions, and very few anticomplementary reactions. They attribute these results to four factors: (1) The employment of a new antigen in a dose some thirty to fifty times less than the anticomplementary unit. (2) A primary incubation of eighteen to twenty hours at 6° to 8° C., followed by ten minutes at 38° C., which greatly favours the fixation of complement by the syphilitic "reagin" in the serum and this extract while maintaining the degree of fixation by serum alone and extract alone. (3) A haemolytic system including small amounts of guinea-pig complement and rabbit-sheep serum, thereby reducing to a minimum the amount of various serum constituents capable of interfering with specific complement fixation. (4) The use of varying amounts of patient's serum which in a small but appreciable percentage of cases increases the specific sensitiveness of the test. Except in cases of trambosia or yaws, they hold that positive reactions are due to syphilis alone. Negative reactions were obtained with the serums of rats, guinea-pigs, and rabbits infected with *Trypanosoma equiperdum*. In 159 cases of leprosy no positive reactions occurred with this method. The authors claim similar results in tuberculosis, pregnancy, diabetes mellitus, malaria, nephritis, leteris, pneumonia, and scarlet fever. They quote the serological study by Rockwood and Sanford of 501 cases of diabetes in which only one apparently false negative reaction and two apparently false positives were obtained by the Kolmer method.

### 110. The Action of the Parathyroid Glands.

W. G. MACCALLUM (*Journ. Amer. Med. Assoc.*, December 6th, 1924, p. 1846) summarizes the results obtained during the last few years from investigations of the parathyroid glands and their relation to disease. It has been shown that extirpation of the glands is especially characterized by an electrical and mechanical hyperexcitability of the nerves, so that minimal impulses give rise to muscular twitchings and spasms. This effect appears to be derived from some change in the circulating blood, since anastomosis of the vessels of a normal animal with those of an animal in violent tetany will reduce the tetanic limb to normal quiescence and restore normal excitability to the nerves concerned. The calcium content of the blood in this tetany has been found to be reduced by about 50 per cent., as was also the case in the spontaneous tetany of infants suffering from rickets. The symptoms of tetany have been cured by intravenous injection of calcium salts, and animals have been kept alive indefinitely after parathyroid extirpation by the addition of calcium to the food. Whether parathyroid extirpation produces an alkalosis is still considered to be uncertain, but it has been asserted that an alkalotic tendency is demonstrable. It has been shown, however, that in parathyroid tetany an excess of phosphates is retained in the body. The tetany due to parathyroid insufficiency has been found to be associated with changes in the teeth and in calcific deposits in the body. He believes that there is no single use of parathyroid therapy rests on a scientific proof, except the use of transplanted glands in tetanic parathyreopriva.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 111. Blood Transfusion in Scarlet Fever.

R. J. WEISSENBACH (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, December 11th, 1924, p. 1686) describes the case of a boy of 14 who for ten years had had symptoms of chronic nephritis, including persistent albuminuria, increase of blood urea (averaging 18 grams per litre), and high blood pressure (maximum 150 mm. and minimum 110 mm.). He had been under treatment for a year when he contracted a severe attack of scarlet fever, with typical pharyngitis and tonsillitis, accompanied by petechial eruption. The urine was scanty and contained 10 eg. of albumin per litre. His mother had just recovered from scarlet fever which had commenced seven weeks earlier, and as the boy's condition was very grave 25 c.cm. of his mother's blood was withdrawn, diluted with 2.5 c.cm. of 10 per cent. sodium citrate solution, and injected hypodermically into his thigh. This single injection sufficed to produce marked improvement; the temperature and pulse rate fell rapidly, and the albuminuria was reduced by 50 per cent. The patient was kept in bed on a light diet, for five weeks, and afterwards resumed his low-protein, chloride-free diet. The blood urea ratio then fell to 0.075 gram per litre, the renal condition being better after the attack of scarlet fever. Weissenbach attributes this unexpected result to the prolonged rest in bed and the strict dietary. He thinks this case shows that the specific virus of scarlet fever does not possess that selective action on the kidney which has been attributed to it. Six months after the attack it was found that the patient had grown nearly 1 inch in height and had gained 4½ lb. in weight. The blood pressure had fallen to a maximum of 130 mm. and a minimum of 80 mm. The rapid improvement that followed the injection of the maternal blood confirms numerous other observations recorded in the last few years.

### 112. Peristolic (Perisystolic) Function of the Stomach.

J. L. ROGATZ (*Amer. Journ. Dis. Children*, November, 1924, p. 582) regards the "peristolic" function of the stomach (concentric contraction) as of practical significance in cases of pylorospasm and habitual vomiting, which condition has been effectively treated by feeding the patients with thick cereals or other concentrated foods of thick consistency. By radiological studies Rogatz has shown that simultaneously with the peristaltic action set up by the ingestion of food peristalsis occurs, the muscular walls of the stomach appearing to surround and grasp its contents. If these are fluid they tend to travel away from the source of pressure and are vomited or regurgitated, but if they are thick and less mobile they are grasped by the gastric musculature and carried towards the pylorus. A definite mechanical relation appears to exist between the infant's stomach wall and its food contents, the ingested food stimulating the muscle wall to surround and grasp it. Just as the vomiting in pylorospasm and habitual vomiting can be explained mechanically on the basis of muscular wall contraction acting upon fluid food, so the vomiting can be controlled by stimulating this peristolic function in its action upon thicker semisolid food. Two cases are recorded to illustrate the striking result obtained with thick cereal feedings (thick milk gruel or mashed potato) in cases of persistent vomiting.

### 113. Acute Empyema and Pulmonary Tuberculosis.

E. SALTZMAN and O. SIEVERS (*Finska Läkarsällskapets Handlingar*, September-October, 1924, p. 781) remark that some life insurance societies assume definitely that an acute empyema predisposes to pulmonary tuberculosis, and class persons who have recovered from an acute empyema with those who have had an attack of pleurisy with a serous effusion. To throw further light on this matter the authors have investigated the after-histories of 324 patients treated for purulent pleurisy in two surgical hospitals in Helsingfors in the period 1902-12. The subsequent observation period ranged from ten to twenty years, and during this interval the fate of 128 was ascertained. It transpired that 19 had died, the cause of death being known to be tuberculosis in 3 cases, and suspected to be so in one other. But as 550 of the 2,078 deaths in Helsingfors in 1916 were due to tuberculosis, the authors do not consider 4 tuberculosis deaths out of a total of 19 deaths as evidence that an acute empyema predisposes to tuberculosis. They found, however, that the mortality from all causes among these 128 persons, who had been discharged from hospital as completely cured after an attack of purulent

pleurisy, was about 20 per cent. above the calculated mortality for the total population at the same ages. The authors find confirmation of their hypothesis, that an acute non-tuberculous empyema does not predispose to pulmonary tuberculosis, in another series of investigations conducted in a sanatorium where they scrutinized the records of 3,557 patients suffering from pulmonary tuberculosis. In only 9 cases could they find a record of empyema, and in as many as 5 of these the empyema had developed after pulmonary tuberculosis had been diagnosed.

### 114.

### Rubella.

G. LINDBERG (*Acta Paediatrica*, October 25th, 1924, p. 1) records his observations on the study of about a thousand cases of rubella, some of which were sporadic, while the rest occurred in a large epidemic at Norrköping (Sweden) during the first months in 1924. The incubation period ranged between seventeen and twenty days. In most cases there were no definite prodromes, the initial symptoms being the characteristic eruption and the glandular swellings. In contrast with measles there was very frequently a complete absence of any feeling of illness. There were, however, occasional exceptions to this rule, especially among adults. The duration of the eruption was usually two or three days. During the epidemic Lindberg found that vasomotor symptoms were pronounced, such as redness of the face and urticaria. The tongue, which was thickly coated with whitish-grey fur, subsequently peeled, and presented an appearance closely resembling that observed in scarlet fever. Definite swelling of the cervical glands was not constant in the epidemic, but was found in 75 per cent. In some cases it was primary, and in one instance the only symptom of rubella. The temperature was not characteristic; although sporadic cases were usually afebrile, in the recent epidemic a temperature of 102° or 104° was not uncommon. Considerable importance has recently been attached to the blood picture in rubella by Naegeli, Feer, and Stöck. At the onset there is a leucopenia which may persist throughout the disease or be converted into a leucocytosis. Plasma cells are very frequently present, and may sometimes form as much as 30 per cent. of all the leucocytes. Lindberg did not observe any complications in the sporadic cases, but during the epidemic he saw six cases of polyarthritis (three in children and three in adults), two cases of stomatitis, and two of protracted pyrexia.

## Surgery.

### 115. Cervical Sympathectomy in Angina Pectoris.

W. S. LEWIS (*Zentralbl. f. Chir.*, November 15th, 1924, p. 2529) records the case of a man, aged 49, the subject of angina pectoris for four years, whose pains had recently become so intense that he had contemplated suicide. The patient was a heavy smoker, but denied syphilitic infection or alcoholism. He spent most of the day in bed, so as to avoid any movement likely to produce an attack of pain. The heart was enlarged in all its diameters. The blood pressure was 198 to 200 mm. Hg (Riva-Rocci), and there was a systolic murmur at the apex. The sympathetic cervical ganglion and stellate ganglion on the left side were removed, and a fortnight later the patient was able to walk about the corridor of the hospital quite comfortably. Twenty-five days after the operation he had a severe psychical trauma, but did not feel any pain in the cardiac region, whereas previously even the slightest emotion had brought on an attack. Three months after the operation there was a general increase in size of the heart, and the patient complained of dyspnoea after a long walk, and also showed some oedema of the face, legs, and lumbar region, especially in the morning. After rest in bed the oedema subsided, and the patient felt well again. When seen three months later the patient stated that he had had no pain since the operation six months previously, but had some dyspnoea on walking, and frequently had oedema, which was cured by lying in bed. The operation had thus relieved the patient from the attacks of pain, but had caused a deterioration of the heart's action. The heart had now been deprived of its regulator or automatic brake in the form of pain conducted along the sympathetic nerve fibres, so that the patient walked or moved faster than the reserve power of his heart allowed. Lewis adds that the surgical treatment of angina pectoris can therefore only be regarded as a palliative operation, the object of which is to relieve the attacks of pain.

**116. Elephantiasis treated by Sympathectomy.**

R. LERICHE (*Lyon Chir.*, November-December, 1924, p. 795), in considering the etiology of elephantiasis, points out that, far from following the usual description given in textbooks, the condition often appears to be spontaneous in origin. Originally it was believed to follow recurrent attacks of lymphangitis, which produce obstruction to the main lymphatic channels, but Leriche doubts whether this is really the case. He asks why the superficial lymphatics are alone affected and the disease localized to the subcutaneous tissues. Below the superficial aponeurosis there is usually no sign of any trouble, and there is frequently no evidence of lymphangitis having been present. In a number of cases he has treated the oedema has often appeared spontaneously and has been found in men or young women. In a case recorded the patient was a woman aged 27; when 16 years of age she had a severe shock, from which the condition appeared to start; this was the only etiological factor to be discovered. It is suggested that a shock causing arrest of the heart's action, and producing an attack of syncope, might be able to originate elephantiasis. This case was treated by femoral sympathectomy, and within two days the circumference of the leg and thigh showed marked diminution. It is possible that the operation produced a communication between the superficial and the deep lymphatics, but it is doubtful if the result would have appeared so rapidly. It has been shown that when dilatation of the superficial arteries is produced experimentally the superficial lymphatics are likewise affected. Leriche thinks that it is probable that the improvement was the result of the division of the sympathetic fibres which control both the arteries and the superficial lymphatic channels.

**117. Myositis Ossificans.**

T. P. NOBLE (*Surg., Gynecol. and Obstet.*, December, 1924, p. 795) reports a group of 18 cases of myositis ossificans, and points out that the traumatic type is important because of its similarity to sarcoma and the danger of mistakes in diagnosis. Three types of the disease are described: (a) when it occurs in early life; (b) following repeated injuries, as in "rider's bone"; and (c) when localized to one site of the body and following a single trauma. The commonest sites of this last group are in the quadriceps and brachialis anticus muscles. The great bulk of the cases occur in males and in early adult life. The condition may follow a blow or, in the arm, result from a posterior dislocation of the elbow-joint. A swelling occurs at the site, resembling a haematoma and causing limitation of movement. It becomes increasingly hard, and can be diagnosed by x-rays. The shadow appears to be separated from the diaphysis by a zone of light which is very constant. In sarcoma it is not present, and, moreover, the shaft of the bone is affected. A sarcoma may feel soft, whereas myositis ossificans is uniformly hard. The situation on the bone is important, for sarcoma occurs more commonly near the epiphyses. Noble adds that the natural tendency of myositis ossificans is towards cessation of growth after some weeks and a variable degree of reabsorption. The treatment is therefore rest at first, and, when the process has ceased, massage and exercise. Operation is only to be considered after six months, and if distinct functional disability exists.

**118. Descending Abscesses in the Neck.**

F. E. PALMER (*Journ. Amer. Med. Assoc.*, December 27th, 1924, p. 2067) remarks that occasionally abscesses in the neck show a tendency to penetrate into the loose collateral tissues and to extend into the mediastinum, thus endangering the life of the patient unless this descending process is recognized early and stopped. He considers that laryngoscopic examination is the only trustworthy means of obtaining an early diagnosis. In the absence of oedema and bulging of the larynx the abscess can usually be opened locally and drained, but Palmer adds that if little or no improvement follows in twelve to thirty-six hours it is necessary to open the mediastinum and seal the spaces by iodoform gauze strips. The author describes this operation in detail and records five illustrative cases.

**119. Left-sided Abdominal Abscess in Appendicitis.**

K. NATHER and A. OCHSNER (*Deut. Zeit. f. Chir.*, November, 1924, p. 114) state that during the last four years nine examples of left-sided abdominal abscesses have occurred among about 700 cases of acute appendicitis at the Zürich University Surgical Clinic. A characteristic feature of the condition is its occurrence in early life, as is exemplified by the fact that four of the nine cases were under 12 years of age. The first symptom is pain in the left side of the abdomen, without anything objective being found on physical examination. Soon, however, definite signs, such as rise of temperature and leucocytosis, make their appearance and indicate the presence of a suppurative process in the abdomen. As the abscess extends it becomes palpable, and local oedema of

the skin of the abdominal wall finally appears. Apart from the risk of septicaemia associated with the presence of chronic suppuration, there are other dangers connected with the condition. A circumscribed abscess may perforate into the abdominal cavity and set up diffuse peritonitis, or the abdominal wall may be so weakened by persistent contact with the pus that after incision of the abscess an intestinal fistula may be formed and persist for an indefinite period. Treatment consists in rest in bed and warm applications. Under such measures the abscess may be completely absorbed, as in two cases recorded by the authors. If conservative treatment fails an incision should be made at the level of the tumour.

**Therapeutics.****120. Treatment of Boils and Carbuncles.**

F. BERNDT (*Zentralbl. f. Chir.*, December 6th, 1924, p. 2583) states that though undoubtedly recovery takes place in a certain number of boils and carbuncles after injection of the patient's own blood, as recently recommended by Löwen, it is uncertain whether this treatment is responsible for the cure, as incisions are made at the same time. Berndt has never employed the method himself, as he regards injections in the neighbourhood of an acute inflammatory focus as a mistake, and quotes a case in which a severe attack of erysipelas followed injection of novocain behind the pinna for a boil in the external auditory meatus. He thinks that the simplest method of treating boils of the face is by application of x-rays, as recommended by Heidenhain at the last German Surgical Congress. Berndt records four illustrative cases, three of which were severe and one mild, successfully treated by this method. For the last thirty years he has employed the following method for treating carbuncles on the back of the neck. A long transverse incision is made over the middle of the carbuncle, followed by a number of perpendicular incisions beginning and ending in healthy skin. A dressing is applied and left on for eight days, when, if necessary, a skin graft is made.

**121. Chicken Serum in Pneumonia.**

FROM experiments on animals H. C. BERGER and J. G. MONTGOMERY (*Arch. Intern. Med.*, December, 1924, p. 667) concluded that chickens tolerated large doses of pneumococci intraperitoneally, and that in normal chicken serum a protective substance against the pneumococcus of Types 1, 2, and 3 was present. This substance deteriorated with time. These results encouraged them to test the value of chicken serum in pneumonia in children. In preparing the serum used the chicken blood was collected in half-gallon jars containing a measured quantity of sodium citrate solution. The serum was removed without pressing the clot. The citrate was removed with calcium and the serum passed through Berkefeld filters. To this fluid, after tests for sterility, was added tricresol, and it was then placed in 100 c.c.m. containers with rubber caps. The report deals with 63 consecutive patients with pneumonia, of whom 41 were treated with the blood or serum of chickens, and 22 received the usual pneumonia treatment but no chicken blood or serum. The authors have now abandoned the use of whole blood because they found that the serum was safer, easier to administer, always available, more comfortable to the patient, and could be administered in larger dosage. The dose of serum employed varied from 50 to 60 c.c.m. intravenously to 350 to 400 c.c.m. intravenously or intramuscularly. The mortality in the cases treated with chicken blood or serum was 12 per cent., against 36 per cent. in the others. They add that the temperature, pulse, and respiration returned to the normal in the first group in one-fourth to one-fifth of the time taken in the second group.

**122. Alcohol Injections into the Gasserian Ganglion.**

G. M. DORRANCE (*Journ. Amer. Med. Assoc.*, November 22nd, 1924, p. 1678) records the results of injections of 85 to 95 per cent. alcohol in eleven cases of trigeminal neuralgia that had been treated during the period February, 1916, to June, 1923. Experiments on dogs had confirmed the opinion that alcohol destroyed many ganglion cells, which were replaced by fibrous tissue, but a large number escaped. He considers that the treatment of these eleven patients has proved conclusively that pain will not return in the majority of cases if anaesthesia in the entire distribution of the fifth nerve persists for a month. Even though sensation returned in several cases, pain did not always follow. Injection of the divisions of the fifth nerve has been much less satisfactory. Dorrance, while still advocating this operation, no longer regards it as a minor one, and considers Frazier's operation of partial or complete division of the posterior root is the operation of choice in true

to douloureux. Alcohol injection, he thinks, is definitely indicated for patients who have had radium treatment for cancer of the face; some of these patients suffer from severe pain, which is completely relieved by injection, provided that the fifth nerve only is involved. Two patients among these eleven cases developed corneal ulcers shortly after alcohol injection, but these healed under treatment. In two cases transient paralysis of the third, fourth, and sixth nerves followed the injection. Dorrance concludes: (1) This treatment usually gives permanent relief, if enough alcohol be injected. (2) The absolute indication is carcinoma of the maxilla or of the tongue. (3) In injection of the nerve trunks or of the ganglion, prognosis may be made in four weeks; anaesthesia which persists for a month is likely to remain. (4) Transient paralysis of the ocular muscles occurs occasionally; it always clears up. (5) Eye complications occur in approximately the same proportion as in division of the root by any other method.

## Radiology and Electrolgy.

### 123. X-ray Diagnosis in Endocrine Diseases.

W. ENGELBACH and A. McMAHON (*Radiological Review*, September-October, 1924, p. 3) state that radiological examinations have not often been made in endocrine disease. Beyond observations of the retarded bone growth in hypothyroidism there has been but little study of the bony changes in other endocrine diseases. The authors have examined over two thousand cases of endocrine disease, and report striking differences in osseous development, both general and local. They find that in uniglandular endocrine deficiencies there are definite variations from the normal bone development sufficiently clear to enable a definite diagnosis to be made in a large percentage of cases. In pluriglandular disturbances they state that it is more difficult to determine the influence of the absence or reduction of two or more hormones. They describe in detail the effects of disease of the various endocrine glands on bony development, and conclude by emphasizing the necessity of further investigation of changes in bone development in pluriglandular syndromes.

### 124. Radium Treatment of Myelogenous Leukaemia.

M. M. STRUMIA (*Journ. of Lab. and Clin. Med.*, November, 1924, p. 106) has studied the effect on the morphology of the blood of radium applied over the long bones in two cases of myelogenous leukaemia. Many investigators believe that radium is the best therapeutic agent in this disease. Strumia applied radium emanations, using the method of pack, the radiating tubes being at a distance of 6 inches from the skin and filtered so as to allow free passage to the penetrating gamma rays. He thinks that it is apparently of little moment where the radium is applied, because the entire body receives a large amount of penetrant rays; of greater importance is the quality of the radiations. In addition to its local effect on leukaemic foci radium appeared to induce a general reaction in the blood. It is suggested that leucotoxic material may be liberated from leucocytes directly affected by radium, or radium emanations, and may be carried into the blood stream by the plasma or blood cells. Radium at first seemed to act as a stimulant for both leucocytes and erythrocytes, particularly if applied in small doses. Following the period of stimulation it manifested destructive action especially on the leucocytes, the order of their disappearance being directly related to their degree of immaturity. The platelets were also greatly reduced by radium, and the coagulation time was proportionately lengthened. Haemocytoblasts or primordial cells (Pappenheim's lymphoidocytes) readily disappeared from the blood. The immature cells of the granulocytic series—myeloblasts, promyelocytes, myelocytes, and metamyelocytes—were more readily and decidedly affected than the immature cells of the lymphocytic series—prolymphocytes and lymphoblasts; the latter acted like mature cells and were considerably more resistant to radium action. Strumia thinks that this probably explains the less effective results obtained in chronic lymphatic leukaemia when treated with radiations. In their reappearance in the blood stream the immature cells followed exactly the opposite order of their disappearance, the most immature forms being the last to reappear.

### 125. Radioscopy in the Diagnosis of Heart Disease.

L. F. BISHOP (*Cuore e Circolazione*, November, 1924, p. 429) states that for some years he has submitted all his patients to x-ray examination. Radioscopy enables one to observe the relative activity of the different cardiac cavities and the pulsation of the large vessels, while radiography leaves a permanent record. Many persons, however, cannot avail themselves of the benefit of radiography owing to the trouble

and expense which it entails. On the other hand, Bishop believes that there is nothing to take the place of radioscopy as a rapid means of diagnosis of heart disease. Care, however, must be taken that it does not lead the observer astray, and it must always be accompanied by other methods of clinical investigation. In exploring cardiac lesions of secondary importance radioscopy is, he thinks, far superior to the stethoscope, and in combination with the electrocardiograph this method can detect at least 30 per cent. of the conditions which would otherwise escape notice. There are numerous examples in daily practice of trained observers pronouncing a heart to be normal when radioscopic examination reveals enlargement or deformity of the cardiac image. Many persons with cardiac lesions of secondary importance are conscious that everything is not right with them and refuse to accept an assurance to the contrary, whereas if the cardiac defect is recognized and explained they feel relieved and are able to tolerate the condition patiently, which was impossible when the nature of their disorder was obscure. Bishop maintains that it should be the duty of all large institutions to employ radioscopy as a routine method, since it will reveal a large number of unsuspected lesions and will thus save a great amount of trouble. It will also occasionally detect conditions in the abdomen or chest which may require prompt surgical intervention to save life. Combined radioscopy, radiographic, and orthodiagraphic examination of morbid conditions will reveal the nature of the affection by the changes shown (a) in the character of the pulsations, (b) in the position of the heart, and (c) in the measurement and form of its borders.

## Obstetrics and Gynaecology.

### 126. Treatment of Pelvic Cancer.

H. SCHMITZ (*Surg., Gynecol. and Obstet.*, December, 1924, p. 775) publishes the five-year results of treatment of 180 cases of primary carcinoma of the female pelvic organs. The grouping "operable" and "inoperable" is abandoned, being too dependent on subjective considerations, and the following groups are distinguished: (1) Cases of clearly localized single growths, without surrounding oedema or infiltration—cases in which diagnosis of malignancy is established by the microscope only. Surgical treatment is here indicated. (2) Cases in which there is doubt of the exact site of the growth, as in cervical cancer and cases where the paravesical tissues are oedematous or doughy. Here the treatment recommended in most instances is x-ray and radium applications with subsequent radical surgical excision. (3) Cases of multiple growths, infiltration of adjacent tissues, fixation of organs; or involvement of regional lymph glands. These require treatment by radium and x-rays. (4) Cases of extensive ulceration and necrosis, with distant metastases, and cases with advanced cachexia. Here radiation is useless, and treatment should be symptomatic. Cases of cervical carcinoma in the second group were treated by radiation without subsequent surgical excision. Of 37 patients in groups (1) and (2), 46 per cent. were living and well after five years; in group (3), comprising 56 patients, 10 per cent. were well; and in group (4) of 47 none had survived. The absolute curability in 180 cases of all groups was 15 per cent. Schmitz concludes that if the percentage of cases suitable or unsuitable for operation is taken into account, the results of radiation compare favourably with those of surgical treatment.

### 127. Myoma and Sarcoma Uteri.

O. FRANKL (*Arch. f. Gynäk.*, October 13th, 1924, p. 554) states that in a period of about fifteen years 1,878 cases of uterine myoma were included among operation specimens in the Pelham clinic in Vienna; during the same time there were 38 cases of sarcoma of the uterus, and 8 cases showing both a sarcoma and a carcinoma of the uterus. Among the 38 cases of sarcoma there were 17 cases in which a pre-existing myoma or myomata could be demonstrated, and 5 in which this pre-existence was probable; in 15 cases there was no evidence of pre-existing myoma. The patients of the second group were older than those of the first, and in general had passed through a larger number of pregnancies. Interstitial myomata appeared to have become sarcomatous more often than subserous or submucous. Sarcomata arising independently presented within the cavity of the uterus in the great majority of cases as tuberos, irregular, or grape formations. Microscopical examination appeared to indicate that in 14 of the 15 cases in which no preceding myoma was present curetting would give material sufficiently characteristic to establish a diagnosis of sarcoma. With one exception this group of cases was characterized clinically by irregular bleeding, which was absent in more than one-quarter of the cases in which a myoma had become sarcomatous.

## 122. Treatment of Puerperal Infection.

H. ROULLAND (*La Gynécologie*, October, 1924, p. 577) discusses current views as to the utility and modes of administration of serum and vaccines in puerperal infections. The effects of serotherapy, he says, are inconstant. Serums should be administered, preferably by the intravenous route, in the earliest stages of infection—that is, at the onset of pyrexia. Since there is no time for preparation of autoserums, polyvalent stock serums must be used. In order to prevent acclimatization of the infective organisms, large doses must be given for a limited period (60 to 100 c.cm. during the first three or four days), and the treatment be then suspended for a while, to be resumed later if necessary. Local applications of serum should also be made, either by introducing each day 50 c.cm. into the uterine cavity, or by leaving there for eight to ten hours a piece of gauze steeped in serum. In cases taking a comparatively benign course Roulland considers vaccines preferable to serums; they have the advantage of not inducing a state of anaphylaxis. Vaccine therapy is useless, and may be dangerous, in states of profound general depression and asthenia, in very acute septicæmias, or when there is cardiac, renal, or adrenal deficiency. At the best antibodies will not be produced for about eight days; recent endeavours to detect the presence of antibodies in the serum of patients who have had antistreptococcal vaccination have been disappointing. In general vaccines are most useful in attenuated infections or in the terminal phases of acute ones. The dose is still largely empirical, but the author prefers to begin with small ones, which are progressively increased. Roulland adds that possibly future vaccine therapy will be local, in accordance with the teaching of Be-rezka, but the value of this method has not yet been established.

## 123. Pituitary Extract in the Third Stage of Labour.

D. GUGGINO (*Rivista d'Obst. e Ginecol. Pratica*, November, 1924, p. 572) describes a case which shows that the injection of pituitary extract at the beginning of the third stage of labour is not always devoid of untoward consequences, though an American observer, using this method in 100 cases, encountered no case of consequent uterine tetanus; he had previously recommended its routine employment before the manual extraction of the placenta. Guggino's patient, a 2-para aged 28, showed some degree of uterine inertia towards the end of the second stage of labour, but gave birth, three hours after administration of a small dose of quinine hydrochloride, to a live child presenting in the second vertex position. Half an hour later, uterine contraction being deficient and Credé's method of expressing the placenta having failed, 1 c.cm. of pituitary extract was injected. Two and a half hours later the placenta was still retained, and the uterus was so firmly retracted as to make manual extraction impossible. Eventually the placenta was removed under morphine and chloroform narcosis.

## Pathology.

## 129. Normal Movements of the Stomach.

E. D. MCCREA, B. A. MCSWINEY, J. W. MORISON, and J. S. B. HALDANE (*Quart. Journ. Exper. Physiol.*, October, 1924, p. 379) have studied the anatomy and physiology of the normal human stomach and describe it as being J-shaped in the upright posture. It consists of two divisions: (1) a fundus and the proximal portion of the corpus—the quiescent reservoir; (2) the distal part of the corpus and pyloric antrum—the active portion. In the erect position air is found under the fundus dome. The incisura angularis is the dividing line between these two physiologically separate portions. The authors found also that active movements begin almost immediately after food has entered the stomach, and some liquid leaves it within the first few minutes of gastric digestion. Peristalsis begins with a series of constrictions encircling the viscus at about the incisura; from this point waves, increasing in depth, travel towards the pylorus—shown on the fluorescent screen as waves over the lesser and greater curvatures. Food which has reached the antrum and is not immediately discharged into the duodenum may be retained for a long time in the now spherical pyloric sac, being often completely cut off from the corpus. In this sac rhythmic concentric contractions begin, diminishing at intervals its capacity and forcing out its contents. Where the contents may not pass into the duodenum, but some may be returned to the corpus. In this case fine waves may be seen on the antrum. The authors term this condition a "two-rabbit" type of stomach; it is found also in the dog and antrum may be either in the position of systole or diastole.

The number of peristaltic contractions present at one time varies from three to four. The time taken to complete one wave was found to be approximately twenty seconds.

## 131. Spontaneous Immunization against Diphtheria.

P. LERIBOLLET and JOANNON (*Paris Méd.*, December 27th, 1924, p. 533) discuss their observation of the spontaneous acquisition of immunity to diphtheria in a children's hospital. It was found that during their stay in hospital children who on admission were susceptible to diphtheria had gradually developed an immunity to this disease. The longer the stay the more likely was this immunity to develop. Many of the children suffered from a mild angina, which the authors suspect was a very slight form of diphtheria, and they think that this was responsible for stimulating the formation of antitoxin in the blood. Children whose beds were situated in the corners of the wards where the amount of light and air was less than in other portions did not develop immunity so frequently. The authors point out that these observations are similar in many respects to those of Dudley, who found that during an epidemic of diphtheria amongst the boys at the Royal Naval College at Greenwich a large number of contacts developed an immunity to the disease without actually suffering from it clinically, and that the longer the stay in the College the greater was the proportion of Schick negatives. They accept Dudley's conclusion that whether infection does or does not occur depends on two main factors—the frequency of the dosage and the intensity of reaction of the individual. They add that there appears to be little doubt that in such diseases as diphtheria and scarlatina, to which our susceptibility is not very high, a spontaneous process of immunization can occur by the inhalation of small, subinfective doses of bacteria.

## 132. Diagnosis of Tuberculosis in Cattle.

RENEWED interest is being shown in the agglutination test as a method for the diagnosis of tuberculosis. P. KARMIAN (*Centralbl. f. Bakt.*, November 15th, 1924, p. 358) publishes some results which he has obtained by comparing the titres of the serums of normal with those of tuberculous cattle. Altogether nine healthy control animals were used and eleven tuberculous ones. All except one of the latter were carefully examined after death to ascertain the extent of the disease; the remaining animal was in a veterinary clinic suffering from open tuberculosis with the bacilli in the sputum. The controls were also examined thoroughly in the slaughterhouse, where the blood was taken. For the agglutination test Fornet's antigen was employed, prepared by mechanical treatment of the bacilli, assisted by extraction of the fatty envelope in an ether vapour bath. The serums were diluted with the antigen itself, dilutions being put up from 1 in 40 to 1 in 5,120. Incubation was maintained for twelve hours and the results read after fifteen minutes at room temperature. The serums of the healthy animals showed an agglutination titre varying from 1 in 40 to 1 in 640; of the tuberculous animals the titres ranged from 1 in 80 to 1 in 5,120, but only four of them showed a higher titre than the highest given by the normals. No relationship was observed between the extent of the lesion and the titre.

... for the diagnosis

## 133. Production of a Staphylococcal Exotoxin.

J. T. PARKER (*Journ. Exper. Med.*, December, 1924, p. 761) has been successful in obtaining a toxic substance from the *Staphylococcus aureus* which has a selective action on the skin of rabbits. It is prepared by growing the organism in a 4 per cent. peptone broth medium, buffered with phosphate, and containing not more than a minimal amount of sugar. After four to six days' growth the culture is filtered through a Berkefeld candle and tested for sterility. Not all strains of *Staphylococcus aureus* were found to produce a toxin; in fact, only four of the twenty-one strains tested did so. When injected intracutaneously into rabbits it gave rise to a circumscribed dark bluish-purple area about 2 to 5 cm. in diameter, which on the following day assumed a yellow colour, and was then surrounded by an additional zone of deep red, about 0.5 to 3 cm. in diameter. On the fifth day the yellow gave place to a brown coloration, and by the twentieth day it was replaced by a dark brown dry scab, which eventually—in four to eight weeks' time—fell off, leaving an ulcer. Curiously enough there was but little evidence of systemic poisoning, and intravenous injections made to determine this point more fully gave rise to variable results. Parker adds that the toxin is extremely labile, being destroyed by heat at 55°C. in one hour. After intracutaneous injection he believes that an antibody is formed in the blood which has a neutralizing effect on the toxin, depriving it of its power to produce the typical skin lesions. So far as could be ascertained the toxins formed by the different strains were identical. The author considers this toxin to be a true exotoxin.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 134. Pernicious Anaemia in Typhoid Fever.

M. STANZANI (*Rif. med.*, November 10th, 1924, p. 1063) states that while much study has been devoted within the last ten years to changes in the leucocytes in typhoid fever, comparatively little has been published about the changes which the red corpuscles undergo in this disease. He has collected from the literature five cases of pernicious anaemia, including one of his own which occurred at the height of typhoid fever. Four were in women and one in a man. The ages ranged from 19 to 48. There was usually no family history, and the personal antecedents were of little importance, except that one patient had had jaundice, another malaria, and a third dysmenorrhoea. In all five cases the onset of the disease occurred in September or October. The anaemia developed in the second or third week of typhoid fever, and was characterized by a rapidly progressive yellow coloration of the face. Different types of temperature were seen—namely, high continued fever, marked daily remissions, irregular pyrexia, and an afebrile stage preceding death. Rose spots were usually absent, whereas vomiting of bile and various haemorrhages, such as epistaxis, gingival bleeding, haematuria, haemat- emesis, and intestinal haemorrhages, were frequent. Three patients recovered and two died. The strain of organism isolated did not show any morphological or biological features to distinguish it from the typical typhoid bacillus. Stanzani's patient was a woman, aged 40, who was admitted to hospital on the thirtieth day of typhoid fever, which she had contracted from nursing her daughter suffering from the disease. The skin and sclerotics were subicteric, and the mucous membranes were anaemic. The urine was scanty, and contained much urobilinogen and traces of indican. Examination of the blood yielded the following results: haemoglobin percentage 28, red cells 1,250,000 per cubic millimetre, leucocytes 2,900. There was intense anisocytosis, and a few megaloblasts and normoblasts were present. The blood serum had a golden yellow colour, which in the course of a few hours assumed a greenish tinge. Naegeli, who had also observed this phenomenon in a case of pernicious anaemia, attributed it to the presence of urobilinogen. The Wassermann reaction was negative. Cultivation of the bile yielded a pure growth of typhoid bacilli, and the Widal reaction was positive. Examination of the gastric juice showed achlorhydria. Gradual recovery took place in the course of the next five months.

### 135. Anginal Attacks in Epidemic Encephalitis.

C. LAUBRY (*Bull. et Mém. Soc. Méd. Hôp. de Paris*, November 27th, 1924, p. 1588), who reports a case in a man aged 60, states that anginal attacks are exceptional in epidemic encephalitis, although pains in the viscera, especially of the abdomen, are frequent. Rectal, peritoneal, and appendicular crises have been recorded, in some cases so severe as to require operation. Anginal attacks appear to be of the same character. They probably indicate involvement of the vago-sympathetic in the encephalitic process. In the subsequent discussion Netter (*Ibid.*, p. 1590), who alluded to the frequency of the abdominal forms of epidemic encephalitis simulating appendicitis or intestinal obstruction, stated that he remembered only one example of anginal attacks, the patient being a man aged 62.

### 136. Gastric Achylia and Anaemia.

K. FABER and H. C. GRAM (*Arch. Intern. Med.*, November, 1924, p. 659) record extensive observations on the relationship between gastric achylia and simple and pernicious anaemia. Fenwick first demonstrated gastric achylia in pernicious anaemia, but he emphasized the atrophy of the gastric mucosa. Faber in 1913 put forward the hypothesis that anaemia, simple and pernicious, was secondary to gastric achylia; A. F. Hurst has supported this view. Of 51 cases of pernicious anaemia Faber and Gram have found gastric achylia in 47; but in 4 cases free hydrochloric acid was found in the gastric juice. The authors consider that these exceptions do not settle the question whether achylia, when found, is of pathogenic importance in regard to the anaemia; they merely show that there must be other possible causes, which at present are obscure. In 4 cases recorded gastric achylia and a normal percentage of haemoglobin were demonstrated twelve years before the onset of pernicious anaemia; achylia was therefore not the result of the pernicious anaemia. Hartman also has recorded pernicious anaemia two or three

years after complete gastrectomy. This would tend to show, according to Faber and Gram, that the cause of the anaemia is to be sought in the intestines, the contents of which are affected by the lack of gastric digestion, whether brought about by achylia or complete gastrectomy. The authors record the results of blood examinations in 90 cases of gastric achylia. The haemoglobin was below normal in 41 per cent. of these cases and in 36.5 per cent. of 63 uncomplicated achylia cases. The anaemia was simple in type, resembling that of chlorosis. The most successful treatment in these cases appeared to be large doses of reduced iron three times a day. The anaemia occurred in both sexes and at all ages; it showed a tendency to recur.

### 137.

### Reinfection in Syphilis.

J. R. DRIVER (*Journ. Amer. Med. Assoc.*, November 29th, 1924, p. 1728), from a study of thirteen cases, concludes that with modern therapy syphilitic reinfection occurs more often than is generally suspected. He asserts that in order to establish a diagnosis of reinfection *Spirochaeta pallida* must have been found in the lesion of the first attack and also in the chancre of the second attack, which must appear at a different site from the first. The blood examined shortly after the appearance of the second chancre, and before the reaction has had time to become positive, shows a negative Wassermann reaction. The interval between the first and second infections in Driver's cases averaged fifteen months, with extremes of from one month to ten years, indicating that the first infection does not confer immunity for any definite period, and that as soon as the first infection is cured a second infection is possible. Driver adds that syphilis is curable provided that an early diagnosis is made and arsenphenamin and mercury injections are immediately started. He considers that in the differential diagnosis of reinfection the presence of spirochaetes with a negative Wassermann reaction eliminates all other possibilities, such as superinfection, auto-inoculation, mucous patch, chancre redux, gumma, and chancreoid. This group of thirteen cases of reinfection in about 5,000 syphilitic patients approximates to the figures of White, who reported 28 in 10,000 cases.

## Surgery.

### 138. Syncope with Convulsions after Operations on the Nose and Throat.

F. J. COLLET (*Arch. Intern. de Laryngol., Otol. et Rhinol.*, December, 1924, p. 1149) records five cases where the not uncommon phenomenon of syncope following operation on the upper air passages was accompanied by the much less usual circumstance of convulsions. The first case was in a man, aged 50, during an operation under cocaine anaesthesia for resection of the septum. Towards the end of the operation there was sudden syncope and convulsions of the muscles of the head, neck, and upper extremities. The attack lasted only about a minute and passed away completely. The second case was in a nervous young woman upon whom electrolysis was being performed for a septal spur. A current of only 2 milliamperes was being used, but the patient fainted and had convulsions of the head, neck, and arms; these lasted only a few seconds, but the syncope lasted several hours. She had previously had a prolonged attack of syncope after witnessing an accident, and was subject to emotional disturbances. A third case was that of a girl, aged 12, who, following a second operation for removal of adenoids, had a certain amount of haemorrhage. On being placed in the sitting position for examination she fainted, and later, after packing the nasopharynx, she fainted again and had similar convulsions to the previous cases. The fourth case was that of a man, aged 32, upon whom, under cocaine anaesthesia, morcellation of the tonsils was performed. Several minutes after the end of the operation the patient became pale, unconscious, with stertorous breathing, followed by violent spasms of the trunk, arms, and legs. These symptoms lasted about five minutes, but the patient remained in a state of shock for several hours, and only gradually returned to full consciousness. In the fifth case, after enucleation of adenoids in a child under ethyl chlorid anaesthesia, there was sudden cessation of respiration followed by convulsions. These and the apnoea lasted less than a minute, but full consciousness was long delayed. It would appear that in the first four cases the convulsions were due to anaemia due to fainting, and in the fifth case to anaemia following cessation of

breathing due either to falling back of the tongue or to the anaesthetic. The author asks why, of the many cases of syncope, so few are associated with convulsions. In his five cases the first and fourth might be due to cocaine, the third to haemorrhage, the second to neither of these; all the patients had undergone a certain amount of emotional disturbance. He thinks that there is some emotional susceptibility in all these cases, and that any indication of this in the history ought to be carefully noted. He thinks it advisable to employ general anaesthesia with preliminary administration of bromides before operating on such individuals.

### 139. Post-operative Acidosis.

F. SCHULZE (*Zentralbl. f. Chir.*, December 6th, 1924, p. 2638), from observations on 150 cases at Bier's clinic in Berlin, found that acidosis occurred in 67 per cent. of all cases after general anaesthesia (ether), in 40 per cent. after lumbar anaesthesia, and in 85 per cent. after local anaesthesia. The incidence of 67 per cent. after general anaesthesia agrees with the figure given in 1895 by Becker, who was the first to draw attention to acidosis following anaesthesia. As acidosis occurs after any operation, irrespective of whether it is performed under general, local, or lumbar anaesthesia, Schulze prefers the term "post-operative" to "post-anaesthetic" acidosis. His experience has shown that no serious importance is to be attached to post-operative acidosis, and therefore it is unnecessary to undertake special preventive measures against it, such as intravenous injection of glucose, which has been warmly recommended. Schulze has recently seen a case in which the intravenous injection of glucose as a cardiac stimulant did not prevent the appearance of acidosis. Acidosis following operation, and its clinical expression, acetonaemia, depend on the patient's age, sex, and constitution, as has been demonstrated by pediatricists in the case of acetonaemia in children. In all probability the acidosis is an indication of a reaction to the shock of the operation. The high incidence of acetonaemia following local anaesthesia (85 per cent.) is in striking contrast to the figure given by Gramen at Stockholm, who found acetonaemia in only 9 per cent. of his cases in which local anaesthesia had been used. The relative infrequency of acetonaemia after operations under lumbar anaesthesia is of practical significance. This method of anaesthesia should be employed for all cases in which there have previously been any signs of acidosis, especially as a pre-existing acetonaemia is increased and prolonged by an operation.

### 140. Biliary Tract Disease.

A. BLALOCK (*Journ. Amer. Med. Assoc.*, December 27th, 1924, p. 2057) reports a clinical study of 735 cases of benign biliary tract disease, with special reference to the presence, position of, or absence of stones. He found that the white races were affected much more frequently than the coloured, and females than males. Pain and indigestion were the most common symptoms, and jaundice was present in 39 per cent. of the cases. In the bacteriological examination positive cultures were obtained in 58 per cent. of the cases, *B. coli* and *B. typhosus* predominating. Cholecystectomy resulted in a shorter stay in hospital and a better condition on discharge than was the case with those in whom the gall bladder had only been drained. More than one operation was needed in 11 per cent. of the cases, and in 89 per cent. of these drainage of the gall bladder had been the first operation. The gall bladder was removed in 49 per cent. of the cases and drained in 51 per cent. of the cases. Of cured and improved patients after cholecystectomy, 39 per cent. of cured and improved patients after drainage, and 79 per cent. of those in whom symptoms recurred had had the gall bladder drained at the original operation. Blalock concludes that the gall bladder should be removed whenever it is definitely diseased, provided that the lengthened anaesthesia is not a contra-indication.

### 141. Epithelioma of the Lip in a Youth.

C. M. RAMIREZ (*Rev. Med. Cubana*, December, 1924, p. 1021) records the case of a youth, aged 17, who six months previously had noticed a slight crack on the right half of the lower lip. The crack gradually became converted into an ulcer and increased in size. A thermo-cautery was then applied, but the ulcer continued to grow more rapidly than before. Antisyphilitic treatment was next instituted, but without any effect. On admission to hospital the ulcer involved the whole of the lower lip and extended to the gums. The regional glands were not affected. The patient was a non-smoker. Microscopical examination showed that the lesion was a squamous-celled epithelioma. The issue of a biopsy has not been recorded. Ramirez is of opinion that if a biopsy had been performed earlier a correct diagnosis with radiotherapy would have offered some prospect of success. When seen by him the growth was inoperable.

## Therapeutics.

### 142. Treatment of Acute Osteomyelitis.

CHARRIER (*Bull. et Mém. Soc. Nat. de Chir.*, December 13th, 1924, p. 1100) records the result of giving vaccines in the treatment of two cases of acute osteomyelitis. In the first case the condition appeared to originate in the lesser trochanter of the femur with oedema, pain, swelling, and loss of movement in the hip-joint; whilst in the second case the disease originated in the lower end of the femur. In both cases the disease was treated with injections of antistaphylococcal vaccine, with immediate relief of the symptoms. The injections were given daily, starting with a dose of 1/2 c.cm. The improvement was so marked and so quickly obtained that operation was found unnecessary; the success of the treatment, therefore, was entirely due to the vaccine. The author insists that if the condition does not improve operative treatment should not be withheld; the sign on which he relied in these cases was diminution of pain. In severe cases, he thinks, the use of vaccine therapy combined with surgical treatment is worthy of trial.

### 143. Salicylate Injections for Psoriasis.

J. F. SMITH (*Brit. Journ. Dermatol. and Syph.*, January, 1925, p. 33) records an experience of fifty-seven cases of psoriasis treated with intravenous injections of sodium salicylate. In order to test the value of the method no local treatment was given, though its use in combination with the injections is advocated. The intravenous administration of 10 c.cm. (with a maximum of 12 c.cm.) of a 20 per cent. solution three times a week for about four or five weeks is the procedure advised. No unpleasant effect was noted so long as the dose did not exceed 3 grams; no symptoms of salicylism occurred, and although exfoliative dermatitis ensued in 6 per cent. of the cases its connexion with the treatment is uncertain. In 16 per cent. of the cases the eruption entirely disappeared, and in 18 per cent. there was an almost complete disappearance, with a distinct improvement in 14 per cent. of the patients; 52 per cent. were either unimproved or worse, but several difficult cases, including one which had resisted a variety of measures, were cleared up by the treatment. The high percentage of failures and the necessity for frequent attendance renders the method unsuitable as a routine treatment, but in selected difficult cases it appears to be of definite value.

### 144. Ovarian and Mammary Preparations.

E. NOVAK (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 2016) contributes a brilliant and rather pessimistic discussion of the value of ovarian therapy. In functional amenorrhoea he considers that, though the indications are theoretically good, the results have not been very striking, even when ovarian therapy has been combined with the use of thyroid and pituitary extracts. He believes that ovarian therapy should not be used until such conditions as incipient tuberculosis, anaemia, or other systemic diseases have been definitely excluded. In treating the vasomotor symptoms associated with the menopause better results have been obtained by using corpus luteum extracts, rather than those derived from the whole ovary. Some relief has been reported from the hot flushes, the vertigo, and headache, but occasionally no good results have been obtained. In dysmenorrhoea, sterility, and the vomiting of pregnancy, he finds that, with few exceptions, very little benefit has been reported. Novak concludes that, though there is little doubt as to the future importance of ovarian therapy, its present value is debatable. In the same issue (p. 2018) W. A. PUCKNER expresses the opinion that there is no definite evidence that the administration of mammary gland preparation is of any value. Inquiries were addressed to gynaecologists, obstetricians, and others who might have been expected to have information with regard to mammary gland preparations, but in no case was a favourable report received.

### 145. Protein Therapy of Infantile Tuberculosis.

E. SUÑER (*La Medicina Ibera*, January 10th, 1925, p. 34) states that he has employed this method since the article by Czerny and Eliasberg on this subject in 1920. The best results were obtained by the use of normal horse serum, and no advantages were observed by reinforcing its action by peptone. As a rule, the injections should start with 1/2 c.cm. daily, and when the tolerance of the individual has been determined the dose should be increased to 1 c.cm., which should be continued until 80 to 100 injections have been given, as recommended by Czerny and Eliasberg. The results were very satisfactory. Suñer differs from Czerny, who considers that tuberculous cachexia is the best indication for protein therapy, and maintains that better results can be obtained by employing the treatment at an earlier stage of the disease.

140. **A Urinary Antiseptic.**

V. LEONARD (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 2035) has investigated the value of oral administration of alkyl derivatives of resorcinol in producing bactericidal urine and disinfection of the urinary tract. He concludes that hexyl resorcinol possesses properties entitling it to be considered an ideal internal urinary antiseptic. He asserts that it is chemically stable, non-toxic, and non-irritating; and that it is excreted unchanged in sufficient concentration to render the urine actively bactericidal in any reaction, though the administration of sodium bicarbonate prevents the secretion of bactericidal urine. Infections due to *Staphylococcus albus* and *aureus*, the streptococcus, and *B. pyocyaneus* yielded promptly and completely to oral administration. Similar results occurred in *B. coli* infections, but persistent treatment is often necessary, as cases with high bacterial counts are extremely resistant and may require local treatment in addition. Failure in complete disinfection may point to the existence of pyelonephritis. Improvement of symptoms may result even with doses too small for thorough disinfection. As the result of standardization (phenyl coefficient) it is claimed that hexyl resorcinol is the most powerful germicide for its degree of non-toxicity yet known.

## Laryngology and Otology.

147. **Naso-pharyngeal Growths.**

SIR W. MILLIGAN (*Journ. of Laryngol. and Otol.*, October, 1924, p. 537) discusses the tumours found in the post-nasal space. Naso-pharyngeal fibromata are rare and almost always occur in young males. They are benign histologically and do not produce metastases, but they pursue what is clinically a malignant course in many cases, infiltrating and extending into neighbouring structures. They may arise from any part of the space except from its posterior wall, and the more anterior the point of origin the softer and more polypoid they are. They may be sessile or pedunculated, and they tend to be extremely vascular. For removal the author recommends a preliminary embedding of tubes of radium emanation, followed by separation of the attachment by a long, highly tempered chisel, passed either through the nares or through a lateral rhinotomy. The great danger in such removal is that of haemorrhage, which may be very profuse, but is much decreased by the preliminary exposure to radium. Diathermy is in some cases a very valuable method of attack. Angiomata are very rare; they do not infiltrate or invade neighbouring structures, and though surgical removal is difficult, yet they respond to radium treatment. Sarcomata appear as extensive growths which invade the neighbouring sinuses, but not the glands until a very late stage. They do not tend to ulcerate, but give rise to profuse haemorrhages. Operative removal is difficult and uncertain, but radium treatment has been followed by almost miraculous disappearance of the tumour in a few days. Endotheliomata, in distinction from sarcomata, are of very slow growth, and may gradually recur time after time following removal. These growths consist mainly of vascular tissue with very little stroma, and are therefore very sensitive to radium treatment, which, followed in some cases by diathermy, is the most satisfactory method of dealing with them. Carcinomata are most disappointing; they are usually diagnosed late, tend to ulcerate quickly, and rapidly become secondarily infected. Three signs point to cancer of the nasopharynx—recurring spontaneous haemorrhage, recurring sero-mucous catarrh of the middle ear, and persistent otitic pain without signs of inflammation—especially when the three signs appear in conjunction. Any operative treatment usually aggravates the condition, and basal therapy has been disappointing. The columnar and basal celled carcinomata are more amenable to radiation, but the resistant squamous-celled carcinoma is most commonly met with. The results of radium and diathermy have been less disappointing than those of surgical measures, and the author believes that in them lies probably the hope of successful treatment of naso-pharyngeal neoplasms.

148. **Peritonsillar Fistula.**

SPALAIKOVITCH of Bordeaux (*Rev. de Laryngol., Rhinol. et Otol.*, September 30th, 1924, p. 589) compares the acute abscess in the lateral pharyngeal wall which may arise from the palatine tonsils, from the retropharyngeal glands, from congenital cysts, or from syphilitic or actinomycotic infections, with the slow, cold production of an abscess cavity and a fistula. The latter is rare and may follow any of the lesions mentioned, or may arise in connexion with dental or alveolar sepsis. The author relates the case of a young woman who had noticed a bad taste in the month, and after anterior had been

canterized and closed for a few days, during which a swelling appeared below the right mandible; this disappeared when the fistula reopened and the discharge of pus recommenced. Later the wisdom tooth of the lower jaw was removed, but was found to be healthy. After eighteen months the fistula was patent with no other abnormal condition in the month. A swelling was felt behind and below the angle of the mandible, and when this was pressed pus in fair quantity was forced out of the fistula. A probe was passed into the fistula and entered a cavity of apparently considerable dimensions. An x-ray photograph showed no abnormality in this region. The fistula was injected with iodoform, and a further x-ray photograph showed a large irregular cavity in contact with the inner face of the mandible. Three days later the fistula closed and has remained so for some considerable time. A further x-ray photograph showed the cavity filled with the opaque liquid and unaltered. The origin of the fistula was doubtful, but syphilis was eliminated; there was no sign of any dental or maxillary lesion, and no previous history of congenital cyst. The author's conclusion is that the fistula arose from chronic tuberculous infection of a gland, one of the group lying against the inner face of the lower jaw; the fistula of an abscess in the submaxillary gland would open through the skin. The author draws attention to the value of iodoform in such cases: it is opaque to x-rays, is entirely non-irritating, and, judging by this case reported, it has some curative action on chronic tuberculous conditions.

149. **Vasomotor Rhinitis.**

R. SONNENSCHNIG and S. J. PEARLMAN (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 1973) contribute a summary of current views about the relationship of the parathyroid glands and calcium metabolism to vasomotor rhinitis. They point out that in this disease the patient gives a history of frequent colds in the head, accompanied by persistent sneezing, and a large amount of thin serous secretion. The nasal mucous membrane is pale and oedematous, and the middle turbinates appear as though fluid is about to exude from them. Some writers have suggested that this disturbance is a form of anaphylaxis due to protein sensitization of one form or another, but in a certain number of cases no such sensitization has been demonstrated. Another cause suggested is irritation by dust, chemical fumes, or feathers, and deficiency in vitamin A has also been suspected. More recently emphasis has been placed on deficiency of the calcium content of the blood as being primarily concerned. The authors doubt whether this calcium content is the only essential factor in vasomotor rhinitis, since in none of their cases was a definite deficiency regularly observed. They find that calcium given intravenously acts probably as a sedative, but that its action when given by the mouth is uncertain. They find little evidence that parathyroid treatment is of any value, but the ultra-violet rays may be beneficial. They urge the importance of further research, using only one therapeutic measure at a time, in order to arrive at more definite conclusions with regard to the value of the various medicaments suggested.

## Obstetrics and Gynaecology.

150. **Prognosis of Pyelitis in Pregnancy.**

H. NAUJOKS (*Zentralbl. f. Gynäk.*, November 22nd, 1924, p. 2581) has been able to trace the subsequent history in 37 of a series of 100 cases of pyelitis of pregnancy, 21 patients being clinically examined two to twenty years after their illness; 23 appeared to have been cured, 8 presented morbid clinical and bacteriological signs, and one had died from recurrence. Every patient with *B. coli* pyelitis examined after three years appeared healthy, both clinically and as regards bacteriological findings; but since they had had recurrences (in some cases at intervals of some years) it seemed that absence of *B. coli* from the urine could not be taken as indicating lasting cure. Of the 23 cured patients, 15 had never experienced a recurrence, although nearly all had undergone subsequent pregnancies. Two of the four who had not become pregnant again had had second attacks of pyelitis, and several of the others had kept well during their pregnancies but had had attacks in between them. From analysis of the history of a small number of cases of renal calculus and pyonephrosis in women, the author is inclined to believe that pyelitis of pregnancy plays an appreciable part in the genesis of these conditions. Although pyelitis is rarely fatal, and not necessarily recurrent, there must be some reserve in the ultimate prognosis. Concerning treatment, it is stated that active measures, such as ureteral catheterization and lavage of the renal pelvis, have been rarely employed, and then without benefit.

## 151. Operative Treatment of Uterine Fibroids.

ROUFFART (*Gynéc. et Obstét.*, No. 6, Tome X, 1924, p. 410) contrasts the treatment of fibroid tumours of the uterus by radiation and by surgery. According to him surgery is the chief method of treatment, and it is advocated even in cases of neurasthenia associated with such tumours, several cases being described to illustrate its efficiency. Radiation, he thinks, is only of use in cases in which the bleeding is ovarian in origin, which may be diagnosed by its periodicity. Irregular or almost continuous bleeding is rarely helped by radiation, the bleeding in these cases being due perhaps to mechanical irritation of the uterine mucosa, alteration in the endometrium, or muscular inertia. According to this reasoning, radiation is of no use after the menopause, and operation is the only course likely to prove beneficial. Surgery is also specially indicated if pain is associated with the tumour, since this usually means some adnexal or appendicular trouble. Other indications for operation include great size of tumour, multifoliation, a sessile submucous tumour accompanied by fetid discharge, tumours likely to cause pressure symptoms, those associated with ascites or rapidly growing and suggesting malignancy, and lastly, some cases where nervous or circulatory disturbances are associated with a fibroid. The prognosis for hysterectomy, in the author's opinion, is so good—the mortality being scarcely 2 per cent.—that he concludes by advising operation in many cases of circulatory, nervous, or urinary disturbances associated with fibroid tumours of the uterus.

## 152. Spontaneous Delivery of a Living Ectopic Foetus at Term.

R. VAUDESAL (*Bull. Soc. d'Obstét. et de Gynéc. de Paris*, 1924, 10, p. 785) records a very unusual termination of ectopic pregnancy. The patient sought admission to a lying-in home for the birth of her first child, being then far on in labour. The foetal head, covered with a thin membrane, was found to project between the posterior vaginal wall and perineum at each "pain." No cervix uteri, dilated or undilated, was detected. The case being regarded as one of cervical atresia, the membrane covering the head was incised, and as an immediate sequel the foetal head was expelled in the occipito-posterior position. The living child weighed 6 lb. On account of slight persistent bleeding, placental extraction was attempted, first by injection of the umbilical cord, then manually. At this moment the body of the uterus was recognized at the side of and independent of the gestation sac. The ectopic nature of the pregnancy was verified at laparotomy. Copious haemorrhage led to ligation of the utero-ovarian pedicles and hysterectomy. The patient died two hours later. Spontaneous vaginal delivery of an ectopic foetus is not very rare, but the cases hitherto recorded have been those of dead foetuses, usually after suppuration in the gestation sac.

## 153. Traumatic Haemorrhage into the Amniotic Fluid.

M. NICCOLÒ (*Rivista d'Obstét. e Ginecol. Pratica*, November, 1924, p. 569) records the case of a robust woman, aged 20, who threw herself about with extreme violence during the pains of the first and second stages of labour. Vaginal examination was first made after twenty-four hours, and the examining finger was stained with viscous chocolate-coloured liquid. The foetus was dead, and no liquor amnii appeared to have escaped spontaneously. Delivery was effected by forceps, and was followed by evacuation of 18 ounces of thick haemorrhagic fluid. The author concludes that the repeated trauma had caused haemorrhage into the liquor amnii, the augmented viscosity of which had increased the dystocia and destroyed the foetus.

## Pathology.

## 154. Immunization against Tuberculosis.

B. WEILL-HALLÉ and R. TURPIN (*Paris Méd.*, January 3rd, 1925, p. 20) summarize the attempts which have been made in the past to produce immunity to tuberculosis, and proceed to describe the method of vaccination which has recently been elaborated by Calmette and Guérin. After a long course of study Calmette has come to the conclusion that in order for anti-tuberculosis immunization to be successful it is absolutely essential to make use of living organisms. No method which involves such a profound alteration in the physico-chemical constitution of the tubercle bacillus as is entailed by treatment with heat, florides, orolecithin, light, ferments, or other means, has, he thinks, any chance of success; these and numerous other ways have been tried, and all have resulted in failure. Calmette observed that tubercle bacilli were altered in certain ways by their passage through the alimentary canal. Proceeding from this observation he tried the effect of cultivating them in a medium to which ox-bile had been added—a medium which is very alkaline and contains a high percentage of lipoids. After 230 subcultures

during a period of thirteen years he has succeeded in so modifying the bacillus that, when injected into animals, it is incapable of giving rise to disease, though its power of producing tuberculosis appears to be unaltered. When injected intravenously into calves in a dose of 100 mg. it gave rise to a typhoid-like condition, from which the animal recovers spontaneously in two to three weeks; no follicular lesions were produced. Such calves were able during the following year or eighteen months to withstand the intravenous injection of 5 mg. of living virulent bacilli without developing tuberculosis, whereas unvaccinated calves died of an acute generalized tuberculosis in twenty-eight to thirty-five days. The living avirulent organisms introduced in the vaccine remained alive in the lymphatic tissue in a latent state without giving rise to tubercles, and the authors believe that this vaccine confers a real immunity. They add that it is of importance to realize that it can be applied only to animals which have never been infected with the tubercle bacillus, since otherwise a serious reaction, similar to Koch's phenomenon, might result. This method is now being applied to infants. On three alternate days during the first week of life the babies are given a centigram of the vaccine by the mouth. Since 1922 more than 300 infants have been vaccinated without any apparent mishaps. As the method is still in the experimental stage it is applied only to those infants who are condemned to live with tuberculous parents. So far it has not been possible to determine what degree of immunity will result, but the authors hope that it will be sufficient to tide the children over the dangerous period of infection, inevitable under our present conditions, and enable them to build up an active immunity to tuberculosis.

## 155. The Relation of Blood Sugar to Starch in Normal Persons.

K. KJØR (*Acta Med. Scand.*, 26, xi, 1924, p. 159) has performed several experiments to determine the relation of the rise in the blood sugar to the ingestion of starch. It has been shown, for instance, that after a meal of glucose, no matter how great the quantity that is given, the blood sugar does not rise beyond a percentage of 0.18; further, the extent of this rise appears to be largely independent of the actual size of the dose given, provided that it be over 20 grams—that is to say, much the same rise occurs after a meal of 20 grams as after one of 400 grams of glucose. Does the same apply to starch? This is the question the author sets out to answer. His tests were made on three young healthy men and on a lad of 19 who was suffering from neurasthenia. For sugar estimations the capillary blood from the ear was chosen and the technique of Hagedorn and Norman Jensen employed. Tests were made every five minutes during the first hour after the test meal, and every ten minutes later on. Starch was given in the form of either white bread, oatmeal, or potatoes. It was first found that a meal of over 10 grams of starch gave rise to an increase in the blood sugar, which showed an absolute increment of 0.012 per cent. Working with larger doses Kjør found that the increase in blood sugar caused by a meal of 20 grams was practically the same as that caused by a meal of 100 grams—a finding in agreement with that recorded in the case of glucose. The average increment in the blood sugar after a dose of 100 grams of starch was 0.055 per cent. It was thought that, though there was no difference in the amount of the rise caused by different doses of starch, there might be a difference in the time of the rise. Here, again, experimental results differed from those expected; the rise was no more rapid after a dose of 100 grams than after one of 14 grams. It was found, however, that there was some relation between the size of the dose and the time during which the sugar curve remained above normal. Thus after doses of less than 50 grams the mean duration of the rise was fifty-four minutes, whereas after doses greater than 50 grams it was seventy minutes. Lastly, by comparing starch—in the form of potatoes—with pure glucose it was found that the rise in the blood sugar was approximately equal for the two substances.

## 156. Pernicious Anaemia and Renal Insufficiency.

R. H. MAJOR (*Johns Hopkins Hospital Bulletin*, December, 1924, p. 390) refers to the work of previous observers on the renal functions in pernicious anaemia; their conclusions varied considerably. In a recent small series of patients the author found that the examination of the urine showed such a low excretion of chlorides as to suggest retention. These patients were given salol-coated sodium chloride tablets in doses varying from 6 to 20 grams daily. In three cases of undoubted pernicious anaemia the addition of large amounts of sodium chloride to a constant diet produced no increase in the excretion of chlorides, though the patients gave no evidence of renal disease. Major thinks that possibly this retention of chlorides in pernicious anaemia is not due to renal disease but to some other cause—something in the nature of a protective mechanism.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 157. Diabetes complicated by Scarlet Fever and Diphtheria.

P. NOBECOURT and L. LEBE (Paris *med.*, November 1st, 1924, p. 360) state that when a diabetic patient contracts an acute infectious disease the two affections may have a reciprocal action upon one another, depending on the character and intensity of the infectious disease, the type of diabetes, and the condition of the patient before the superposition of the acute infection. They record the case of a girl, aged 14, suffering from diabetes mellitus, who first contracted scarlet fever and then diphtheria without the acute infectious appearing to have any effect on the diabetes or the diabetes modifying the acute infections. They allude to a case reported by Lereboullet of a girl, aged 11, suffering from diabetes, who contracted measles without the course of the diabetes being affected by the intercurrent disease. On the other hand, cases are on record of diabetic children contracting mumps, varicella, and measles, by which the diabetes was aggravated, the acute infection being rendered remarkably severe.

### 158. Syphilis and Tuberculosis.

G. POGGIO (*Clin. Med. Italiana*, September-October, 1924, p. 162), as the result of a careful analysis of twenty-four cases of combined syphilis and tuberculosis (tuberculous subjects who became infected with syphilis and vice versa), says that syphilitic lesions may be found in tuberculous lungs, but that their diagnosis, clinical and radiological, is very difficult, especially where there is much pulmonary fibrosis. Tuberculosis and syphilis may occur as a combined lesion or side by side. Syphilis superimposed on tuberculosis aggravates the tuberculous process. Pulmonary tuberculosis developing in a syphilitic patient runs a different course, depending on the degree of the resistance to the bacillary infection and the activity of the two infections. Poggio adds that the pulmonary fibrosis seen in old syphilitics is not due to the sclerogenic action of the syphilitic virus, but to the action against tubercle. An old syphilitic may in the anatomical progress of the disease gain benefit from increased resistance to tuberculosis.

### 159. Syphilis of the Stomach.

R. BENSANDE and L. RIVET (*Journ. de Méd. et de Chir. Prat.*, December 10th, 1924, p. 845) review the literature of this subject and quote Fournier's observation that gastric syphilis, although very rare, is less uncommon than has been thought. Chiari made 243 autopsies (143 cases of congenital syphilis and 98 of acquired syphilis) and found only 3 cases of definitely specific lesions—2 cases of gumma and 1 of diffuse infiltration. Some authors believe that many gastric ulcers originate as gummata. Extensive syphilitic ulceration may result in "bour-glass stomach," through cicatricial contraction. In other cases pyloric stenosis may produce achlorhydria, progressive emaciation, and other symptoms of carcinoma. Hayem, Hemminger, and Stokes have recorded cases in which the diagnosis of syphilis was made only after histological examination of a surgical specimen. Several authors have found gastric ulcers (sometimes associated with haematemesis and melæna) in cases in which the pain had been attributed to the gastric crises of tabes, from which the patients were suffering. Syphilitic gastritis may occur in cases of congenital syphilis, accompanied by intractable diarrhoea or melæna: the great majority of these patients succumb, but in some cases mercurialunctions are very beneficial. Mariano and Castex have described typical gastric ulcers which were due to congenital syphilis. Gastritis occurs also in the course of both secondary and tertiary syphilis. The latter has been well described by Fournier, who has found that the typical symptoms—pain, vomiting, anaemia, and progressive emaciation—subside quickly when mercury and iodides are given, although other drugs may not be tolerated. The clinical signs of gastric syphilis are essentially polymorphic, and the diagnosis is consequently difficult unless careful investigations of the previous history and the blood serum, together with radiocopy of the stomach, are made. The rapid improvement under antisyphilitic treatment will confirm the diagnosis, as in the case described in our issue of December 13th, 1924 (*Epitome*, para. 467). Prognosis is very grave in congenital syphilitic gastritis, and in all cases in which early diagnosis has not been made, especially in the tertiary stage. Treatment by mercury and iodides by the mouth is usually successful; but if not tolerated, mercurial

unctions or arsouchenzol should be prescribed. Bismuth is useful in many cases, both as a gastric sedative and as an antisyphilitic. Surgical treatment may be required in cases of perforation or fistula or in dense fibrous stenosis which does not yield to medicinal treatment.

### 160. Relation of Catarrhal to Salvarsan Jaundice.

E. GUNDERSEN (*Norsk. Mag. f. Laegevidenskaben*, November, 1924, p. 938) draws attention to the great variations from time to time in the incidence of both catarrhal jaundice and jaundice in the subjects of syphilis. He records one case in which there was a definite causal relationship between salvarsan medication and the development of jaundice in a syphilitic patient, but he is very sceptical as to the culpability of salvarsan in many cases of jaundice in these patients. He has collected the records of the patients treated for syphilis in the skin department of the Rikshospital in Oslo (Christiania) during the period 1877-1923. Of more than 6,000 treated in this period, 36 suffered from jaundice. In the period 1877-84 (1,545 cases) there was only one case of jaundice. In the period 1885-1900 (2,572 cases) there were 22 cases of jaundice. In the period 1901-15 (1,300 cases) there was not a single case of jaundice. In the period 1916-23 (669 cases) there were 13 cases of jaundice. A study of the notifications of catarrhal jaundice in the general population in Oslo showed similar variations, which variations corresponded roughly with those observed in the case of syphilitic patients suffering from jaundice. Hence he concludes that the jaundice of syphilitics may often be independent of their syphilis.

### 161. Perforating Ulcer of the Foot after Encephalitis Lethargica.

N. SAMAJA (*Clin. Med. Italiana*, September-October, 1924, p. 128) reports the case of a man, aged 44, who had been under his care for three years with symptoms of encephalitis lethargica, mental confusion, Parkinsonian syndrome, and perforating ulcer of the left plantar region. After reviewing the various causes of perforating ulcer the author concludes that in this case the cause of the ulcer was the encephalitis. Some cases of perforating ulcer have been recorded in association with paralysis agitans, and cases of encephalitis with trophic lesions have also been described. The author supplies an extensive bibliographical appendix.

## Surgery.

### 162. Genito-urinary Tuberculosis in the Male.

J. WELFELD (*Urol. and Cut. Review*, December, 1924, p. 708) states that genito-urinary tuberculosis in the male is most frequent in adult life. It is rare in old age, but occurs to some extent in infancy and childhood. Most of the cases are found between 25 and 50. The mode of infection of the genital organs by the tubercle bacillus may be in one of the four following ways: (1) The infection may spread by the blood, the bacilli coming from any focus in the organism. (2) The bacillus may gain entrance from without, travel up the urethra as far as the verumontanum, and then invade the vas deferens. (3) The infection may have a urinary origin, the bacilli descending from the kidneys into the bladder, from the bladder to the urethra, and thence to the genital organs. (4) The bacilli primarily developed in one of the glands of the spermatic system, the prostate, or seminal vesicles, follow a retrograde route to reach the testicle. Tuberculosis of the genitals evolves like tuberculosis elsewhere, passing successively through the follicular and tubercle stages to terminate by fibrous regression or caseous degeneration with suppuration and fistulae. Scrotal lesions do not appear until the tuberculous evolution is well advanced. If the primary genital lesion is in the epididymis propagation to the testicle takes place through the body of Highmore. The vas deferens, vesiculae seminales, and prostate are almost constantly infiltrated with tubercles in the course of genital tuberculosis. The vesiculae seminales are particularly attacked by tuberculosis of the massive and infiltrated nodular type. In the prostate there are either tuberculous granulations around the excretory canals or large conglomerate tubercles. Of 125 cases of genital tuberculosis recently observed by Schultz among 14,086 autopsies the prostate was involved in 83.2 per cent., the vesiculae seminales in 64.4 per cent., and the epididymis in 52.8 per cent. In 28 per cent. the prostate was

the only genital organ affected, and in 18.4 per cent. it was the only organ attacked in the whole genito-urinary system. The clinical course of genital tuberculosis is essentially chronic, and terminates in suppuration or fibrous induration. The diagnosis is made by (1) general examination, (2) cystoscopy, (3) search for tubercle bacilli in the urine, (4) x rays, (5) specific reaction tests. Wellfeld adds that genital tuberculosis may be cured without operation in about 50 per cent. of cases as the result of hygiene, rest, climate, and heliotherapy, but such treatment is tedious and expensive, whereas surgical intervention is the rational method of treatment in established genital tuberculosis. Conservative procedures consist in partial operations, interstitial or peripheral injections, curetting, or deep cauterizations. The radical methods are epididymectomy and complete removal of the genital tract.

#### 163. Haematoma of the Abdominal Wall in Advanced Life.

K. BLOND (*Deut. f. Chir.*, December, 1924, p. 372) states that there is no uniform nomenclature for rupture of the rectus abdominis and the epigastric artery or its branches. Wohlgenuth was able to collect 127 cases of rupture of the rectus abdominis from the literature down to 1923: 107 of these occurred in young and vigorous men who were mostly gymnasts, soldiers, and riders, who ruptured their rectus during their occupations. Such cases do not present any etiological or clinical difficulties, and, as Hilgenreiner points out, are not really spontaneous ruptures. True spontaneous ruptures are found in typhoid fever and other infectious diseases, as well as in burns, frost-bites, labour, the puerperium, and in advanced life. While obstetrical trauma offers a sufficiently plausible explanation of the ruptures occurring in labour or the puerperium, the etiology of haematoma in advanced life, of which Hilgenreiner in 1923 could find only seven instances on record, is obscure. In none of those seven cases, nor in one reported by Hilgenreiner himself and one by Reuner in 1924, was the condition diagnosed correctly before operation. The violence of the onset simulated intestinal obstruction in one case (Lambrechtson), in three cases torsion of an ovarian tumour (Wohlgenuth, Ehrenfest, and so choelithiasis (Körte), in one case a case in a woman, aged 73, which

was remarkable for the fact that the onset was not sudden but gradual, with the formation of a tumour the size of a child's head in the left hypochondrium. Operation under local anaesthesia showed that its contents were blood-clot and partially organized blood. Complete recovery took place. Blood maintains that spontaneous rupture of the rectus abdominis and epigastric artery occurs much more frequently than is supposed, and that probably many patients do not seek advice when the symptoms are not violent, as the haematoma is usually absorbed spontaneously. The question whether the rupture of the muscle or that of the artery is primary is still undecided. Blood suggests that rupture of the elastic fibres in the vessel wall is the primary lesion, in view of the fact that damage to the elastic fibres in the skin is frequent in typhoid fever and arterio-sclerosis.

#### 164. Perigastritis.

P. ZANDER (*Zentralbl. f. Chir.*, November 29th, 1924, p. 2632), who refers to the recent paper on this subject by Doberer (*Epitome*, December 6th, 1924, para. 445), states that during recent years he has always found the same type of lesions as this observer—namely, adhesions affecting not only the gall bladder but also the stomach, and frequently associated with thickening of the pylorus. As the gastric symptoms predominated in seven out of thirty-three cases of so-called pericholecystitis and perigastritis, resection of the pyloric portion of the stomach was performed. Histological examination in these cases showed the picture of chronic gastritis described by Konjetzny. The findings in the gall bladder were microscopically and bacteriologically negative. The adhesions were always more marked on the posterior surface than on the anterior surface of the stomach. In many cases the whole of the bursa omentalis was obliterated. A number of the milder cases on histological examination showed only very slight changes in the stomach wall and no lesions whatever in the gall bladder, so that it occurred to Zander that the extensive adhesions were not primarily due to the gall bladder or stomach but to the pancreas. Zander maintains that the pancreas is much more frequently the seat of disease than is supposed. Although surgeons and the form of fatty necrosis, this is merely the end-result, and little is known of mild attacks of pancreatitis. Zander suggests that an inflammatory disease of the pancreas in the form of serous pancreatitis is responsible for perigastritis, though it cannot be determined at present whether the pancreatitis is primary or caused by a previous infection of the

gall bladder or stomach. In many cases this hypothesis of pancreatic disease explains the distribution of the adhesions on the posterior surface of the stomach. Zander records an illustrative case of perigastritis in a woman, aged 44, in whom laparotomy showed evidence of a mild attack of acute pancreatitis without any signs of pancreatic necrosis.

## Therapeutics.

#### 165. Treatment of Shock by Glucose and Insulin.

D. FISHER and M. SNELL (*Journ. Amer. Med. Assoc.*, December 13th, 1924, p. 1906) report the treatment of three cases of surgical shock by subcutaneous injections of insulin, glucose being administered intravenously. A more rapid cessation of the symptoms followed than had been obtained by any other method of treatment. The authors discuss the mechanism of shock, with especial reference to the thyroid gland, suprarenals, the brain, liver, and the muscles. Other investigators have shown that a correlation exists between the blood sugar level and the physical condition. Runners in a Marathon race were examined, and it was found that those with a normal blood sugar content showed no symptoms or signs of shock, whereas in the case of four runners who were markedly prostrated there was a pronounced degree of hypoglycaemia. Fisher and Snell, arguing from these investigations, have devised a method whereby the body can be furnished with a substance that will give rise to an improved supply of energy, maintaining it so long as may be necessary. They had previously tried glucose intravenously, but they now find that the combined use of glucose and insulin is far superior. Their procedure included the gradual intravenous administration of 1,000 c.cm. of a 10 per cent. solution of glucose, and five minutes after the introduction started 15 units of U-20 insulin were given subcutaneously. The injection of glucose was regulated to take one hour for the complete flow, and at the end of this time another 15 units of insulin were given. The patients began to react within an hour, and a few hours later were completely free from any sign of shock.

#### 166. Danger of Indiscriminate Thyroid Medication.

E. MOSLER (*Deut. med. Woch.*, December 12th, 1924, p. 1752) gives an account of six cases in which the administration of thyroid preparations for the cure of obesity caused alarming symptoms. These consisted of great restlessness and mental instability, excessive perspiration, palpitation of the heart, with a rapid pulse, dyspnoea, and cyanosis. He had known all the patients for years and had not ventured to give them thyroid extracts, which they subsequently obtained elsewhere. The author points out the danger of using thyroid medication rather than strict dieting as a means of rapidly reducing weight. Though it is more difficult to teach overfed patients self-denial at table than to let them give full play to their appetites, using thyroid tablets to reduce their weight, the author expresses profound distrust of the latter procedure, which sooner or later may prove disastrous. He has found that the nervous excitation provoked by thyroid extract may last for weeks.

#### 167. Treatment of Diphtheria Carriers by X Rays.

D. KAHN (*Amer. Journ. Roentgenol.*, October, 1924, p. 343) alludes to his previous paper in which he had reported that of 185 refractory diphtheria carriers subjected to Roentgen radiation 147 were released from quarantine through negative culture findings, while the remaining 38 were released through negative virulence tests. No case required more than four treatments, and the average number of treatments given was 1.4. In the present paper Kahn relates that 152 of the original 185 were recultivated ninety days after release from quarantine, and only 25 showed a positive morphological culture, while not a single one showed a virulent diphtheria organism. In a second series of 23 cases negative results were obtained after one or at most two Roentgen treatments. The patients in the second series were treated with a broad focus Coolidge tube, 10 in. focal skin distance, 7 in. spark-gap, 5 ma. filtered through 3 mm. aluminium. Both tonsils and the post-nasal space were treated at one sitting, which lasted four minutes. The interval between successive treatments varied between ten and fourteen days. Kahn maintains that this method has the following advantages over tonsillectomy in the treatment of diphtheria carriers: (1) The possibility of 100 per cent. cure. (2) It is absolutely painless. (3) It requires no anaesthetic. (4) It takes up the minimum amount of the patient's time and gives him the maximum degree of comfort. (5) The absence of any danger, provided the treatment is given by a competent Roentgen therapist. Kahn does not claim any bactericidal effect for x-rays, but believes the results obtained are due to the fact that the tissues of the

throat and naso-pharynx are altered to such a degree that instead of being a suitable soil for the propagation of bacilli it becomes decidedly unsuitable.

#### 168. Corpus Luteum Therapy.

B. SOLOMONS and J. W. B. GATENBY (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1924, p. 580) make the following statements with regard to treatment of gynaecological conditions by administration of corpus luteum extract. This extract, in common with other glandular extracts, has little effect on menorrhagia or metrorrhagia. In dysmenorrhoea it is occasionally efficacious, given either in doses of gr. v thrice daily throughout the month, or hypodermically during or between the menses. It is an effective therapeutic agent in cases of scanty or absent menstruation. In the unmarried, in whom oligomenorrhoea may be accompanied by obesity, it may be combined with thyroid extract; the hypodermic injection of gr. v daily for fourteen days is recommended in some cases. In cases of scanty menstruation in the married, which is usually associated with sterility, treatment by corpus luteum is of great service; in three-quarters of the cases (cases of organic lesions excluded) pregnancy followed. Five grains are given in a capsule twice daily for a week, then thrice daily. Later the dose is increased two or three fold and the course of treatment lasts six months. At the climacteric corpus luteum therapy is of little avail; but its administration is sometimes successful in preventing abortion or premature birth. Bovine liquor folliculi given by the mouth appears to possess no therapeutic value in women.

### Neurology and Psychology.

#### 169. Neurasthenia and Suprarenal Deficiency.

LÉOPOLD-LÉVI (*La Vie Médicale*, December 19th, 1924, p. 1999) recapitulates the salient points of suprarenal deficiency, both experimental and pathological, with special reference to psycho-neurotic symptoms. He describes in detail 10 cases (8 women and 2 men) who suffered from profound neurasthenia, in some cases amounting to melancholia, with suicidal impulses. One man had contracted malaria in the Dardanelles and had a feebly positive Wassermann reaction after a full course of "grey oil" and arsenobenzol. All the patients improved rapidly after oral or hypodermic administration of powdered suprarenal gland, 0.25 cg. to 1 gram daily. Some of the patients appeared to suffer from congenital suprarenal deficiency (two were sisters), and several other patients presented evidence of latent tuberculosis. In some of the women suprarenal deficiency was associated with ovarian deficiency. In such cases Léopold-Lévi suggests the administration of ovarian extract together with suprarenal powder or extract. Several patients had been ill for a long time—three to seventeen years—but these recovered quickly under treatment.

#### 170. Mongolism.

T. BRUSHFIELD (*Brit. Journ. Child. Dis.*, October-December, 1924, 241), in his Cambridge M.D. thesis, states that 177 cases of mongolism were admitted to the Fountain Mental Hospital from 1914 to 1924—98 were males and 79 females; all were in the first decade of life. In 19 cases there was a neurotic heredity, and in 8 a family history of intemperance. In the remainder nothing abnormal was discovered in the family history. Of 157 in which details were available 29 were first-born, 69 last-born, 33 one of the last three, and 14 were only children. In 64 out of 96 cases the mother's age was 39 and over, and in 75 out of 96 cases the father's age was 40 and over. Ill health, privation, or overwork of the mothers was noted in 34 per cent. of the 177 cases. The average number of admissions during the war years was 14, as compared with an average of 5 during the period 1901-21, excluding the war years. Mongols, like other varieties of aments, can be divided into the three groups of idiots, imbeciles, and feeble-minded, the degree of amentia being proportional to the number of mongolian characteristics. As regards the prognosis Brushfield emphasizes the following points: (1) The large number of deaths associated with inflammation of the mucous membranes. (2) The high incidence of congenital malformation of the heart. (3) The lack of response to any therapeutic measures. (4) The general clumsiness of the body and limbs which prevents a mongol taking part in the healthy exercises normal to the child. The average age at death was 7 years among 24 males, and 6 years among 20 females. D. M. BERRY (*ibid.*, p. 259), from a study of 50 cases of mongolian imbecility at the Hospital for Sick Children, Great Ormond Street, comes to the conclusion that there is very little to support the pre-war theory that mongolism is due to the mother reaching the end of the child-bearing period, as over half the cases were first and

second children. On the other hand, much evidence was obtained that the father was sexually impaired, as in two-thirds of the cases he had served in the army or navy, and in nearly a half he had suffered from shell shock, while the mothers were young and healthy.

#### 171. Tabes Diabetica.

R. H. MAJOR (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 2007) reports a case of the rare condition termed "tabes diabetica." Sandmeyer and Williamson have shown that in diabetes mellitus a degeneration of the posterior columns may occur, which resembles closely the lesion found in tabes dorsalis. In the case reported there was the initial difficulty of deciding whether the patient had diabetes mellitus, complicated by tabes dorsalis, or whether he had tabes diabetica. The patient, aged 50, was admitted with the diagnosis of diabetes; he had been treated for diabetes six years previously, and four years after commencing treatment he became unsteady in gait and lost control of his legs when walking in the dark or downstairs. Tingling of the arms and legs developed and sharp lightning pains in the legs also. He became very irritable; attacks of mental depression occurred, and there was almost complete loss of sexual power. The knee-jerks were slightly exaggerated on both sides and ankle clonus was present; Westphal's sign was negative, whereas Romberg's sign was markedly positive. Over the chest, abdomen, thighs, shoulders, back, tips of the fingers, and soles of the feet there were areas of diminished sensation to touch and pain. Under treatment by doting and insulin he improved rapidly, the ataxia disappeared, and he was able to walk normally. The pupils, which had previously reacted very sluggishly to light, but more actively to accommodation, became more normal, and the areas of sensory disturbance disappeared. Major finds it difficult to believe that this patient could have had as much degeneration of the posterior columns as described by Sandmeyer and Williamson and have recovered so promptly from his tabetic symptoms under simple diabetic and insulin treatment.

### Obstetrics and Gynaecology.

#### 172. Tumours containing Ectopic Müllerian Elements.

K. V. BAILEY (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1924, p. 539), in a paper based on a study of twenty cases of "adenomyoma" found in the female pelvis elsewhere than in the uterine mucosa, deals with the etiology, classification, and life-history of the tumours described by Sampson and others as containing endometrial menstruating tissue and giving rise to perforating, haemorrhagic, or "chocolate" cysts. Examples of such tumours have been described as "adenomyoma of the recto-vaginal septum"; before Sampson's report of their endometrial inclusions they had been regarded as due to serosal ingrowths or to congenital Müllerian relics. Blair Bell has suggested the name "endometrioma." Bailey points out that the aberrant epithelial inclusions are of two types—"endometrial" and "Fallopian"—which are histologically distinguishable; he describes the life-history of each. The genesis of both types lies in an abnormal retrograde passage of menstrual blood along the Fallopian tubes into the pelvic cavity, so that either (1) endometrial epithelial cells or (2) Fallopian tube epithelial cells are deposited on the surface of the pelvic organs. The epithelial cells penetrate the organs and erode them, menstruating concurrently with the uterine endometrium. The resultant tumour is of Bailey's first or second type, according to the origin of the epithelial inclusions; the second, or Fallopian tube, type reacts less to menstruation and is less invasive than the endometrial or first type. As a result of histological study Bailey reports six successive stages in the development of the endometrial type of tumour. In the first stage small endometrial gland spaces, partially surrounded by a fibrin matrix containing clumps of cells like those of endometrial stroma, are deposited over the ovarian surface. Subsequently excavation and erosion of the organ leads to the production of a chocolate-coloured seam extending from the surface to the interior. Later part of this seam becomes distended by the products of menstruation, and finally the organ may be transformed into a sac filled with chocolate-like or tarry fluid. In the Fallopian tube type penetration is less and cyst formation is absent, being replaced by diffuse haemorrhagic surface erosion with adhesions. Unlike the former type, this type has not been found to penetrate the corpus uteri from without. Bailey is unable to agree with Sampson that the affected ovary acts as a hot-bed or incubator when other pelvic organs are secondarily attacked by the tumour. He believes that each pelvic invasion occurs at approximately the same time, and

that adhesions are formed at a much earlier stage than that of perforation of a chocolate cyst. He suggests the name of "ectopic müllerianoma" as embracing both the oömetrial and Fallopian tube types of tumour. His description of retrograde passage of menstrual blood along the oviducts is supported by his microscopical examinations of unclamped specimens removed at operation, by observations of Sampson, Minard, and others at operation, and by the earlier microscopical work of Czystowicz.

#### 173. The Operative Treatment of Fibromyomata.

J. HALBAN (*Zentralbl. f. Gynäk.*, December 6th, 1924, p. 2674) discusses the question of the type of operation preferable in myomatous conditions of the uterus. Of supravaginal hysterectomy, vaginal hysterectomy, and total extirpation by the abdominal route, the author favours one or other of the first two, and only uses the third method in complicated cases. He gives statistics to show that the mortality by the third method is much greater. He lays stress on the value of vaginal hysterectomy, for which he claims a mortality of nil in 254 cases. He points out the short duration, the lesser degree of shock necessitated, and the easy technique of this operation; he therefore recommends it in the majority of cases.

#### 174. Scopolamine-Morphine in Obstetrics.

MARGARET H. D. LIN (*National Med. Journ. of China*, December, 1924, p. 377) gives an account of the use of scopolamine-morphine in seven years' practice in China, covering more than 500 cases. She has encountered no ill effects, and refers particularly to the avoidance of perineal tears owing to the slow delivery of the head. Other advantages reported include the prevention of post-partum shock, stimulation of the maternal and foetal circulations, and the absence of any post-anaesthetic reaction. A warning is issued against the use of impure scopolamine containing atropine. A table of the antagonistic action of morphine and atropine is appended.

#### 175. Acute Hydramnios.

ACCORDING TO L. M. RANDALL (*Amer. Journ. Obstet. and Gynecol.*, December, 1924, p. 766), acute hydramnios is frequently associated with some foetal anomaly or with multiple pregnancy (especially uniovular), or with both. For the mother the prognosis is uniformly good, but for the foetus bad. Krabul found that of the infants in 291 cases 103 were born dead, 11 lived, and only 3 were healthy. The case is recorded of a 2-para, aged 23, who in the sixth month of pregnancy had hydramnios, which increased so considerably within ten days as to necessitate rupture of the membranes. About 10 ounces of clear fluid escaped, and a foetus weighing 1½ lb. was delivered. A similar amount of liquor amni escaped after rupture of a second sac, and the second foetus weighed about the same. A third and tensor sac was now ruptured, giving issue to more than 10 pints of fluid, and a third male infant was born. The mother manifested a considerable degree of shock, although the flow of liquor amni was rendered as slow as possible by keeping a hand in the vagina. The triplets were attached to a single placenta.

### Pathology.

#### 176. The Absorption of Bacteriophage by Bacteria.

GERTRUD MEISZNER (*Zentralbl. f. Bakt.*, December 30th, 1924, p. 489) has been engaged in a quantitative study of the absorption capacity of bacteria for the bacteriophage. Three lysins were used—one active against *Shiga*, and the third against cholera. In mixing a loopful of culture with 3 to 5 c.c.m. of lysin, allowing absorption to proceed for twenty-four hours in the cold—at a temperature of 0° to 8° C.—centrifuging for twenty minutes at high speed, and estimating the lytic strength of the supernatant fluid by plating out on agar a mixture of 0.1 c.c.m., diluted or not as the case might require, and 2 drops of a freshly prepared suspension of the susceptible homologous organisms in broth. Briefly, it was found that no organism other than the one against which the bacteriophage was active could remove the bacteriophage; thus a Flexner bacteriophage was not absorbed by a cholera vibrio, though it was completely absorbed by its homologous organism. Still more striking, however, was the fact that only the susceptible strain of the homologous organism was able to absorb it; the complete absence of absorption by the resistant strain, but after treatment with it the bacteriophage was even stronger untreated bacteriophage was 185; after absorption with the susceptible strain it had been reduced to 8, whereas after absorption with the resistant strain it had increased to 2,850.

These observations were made upon both the Flexner and the Shiga lysins; in the case of the cholera one the results were not so distinct, mostly owing to the weakness of the lysin. The bacteria were still able to absorb the lysin after being heated to 100° C. for one hour, and not till they had been autoclaved at 120° C. for the same time was this power destroyed. The combining activity of the susceptible bacteria was very strong; this was tested by allowing absorption to proceed in the usual way, centrifuging the bacteria, adding to them another quantum of lysin, centrifuging again after a day, adding fresh lysin, and so on, till the bacteria were unable to absorb any more. Even after nine successive additions of lysin they were found to be still capable of absorbing the active principle. By repeating the experiment with 0.1 of a loopful of culture instead of with a whole loopful, it was found that after seven treatments with lysin their absorption capacity became exhausted. Bacterial extracts were found to be unable to absorb lysin. From these results the author concludes that the absorption of the lysin is due to the presence of specific receptors in the bacteria, that these receptors are present in the lysin-susceptible bacteria and absent in the lysin-resistant ones, and that the reaction is a chemical one, closely analogous with that of the absorption of agglutinins.

#### 177. Basal Metabolism and the Emotions.

L. H. ZIEGLER and B. S. LEVINE (*Amer. Journ. Med. Sci.*, January, 1925, p. 68), having observed that the basal metabolism readings of neurotic patients without goitre were sometimes high, investigated the effect of emotions on the basal metabolism. The Tissot-Haldane method of determining the basal metabolic rate was applied to individuals who were known to be free from thyroid disease, but to have had past emotional disturbances. The conclusions reached were as follows. The metabolic rate was increased when the attention of the patients was directed to emotion-producing events connected with the past. The most frequent responses to such stimuli were small changes in the colour of the skin, slight alterations in the rate and amplitude of respiration, and fine tremors. In some patients increase in metabolism without objective reactions was not accompanied by any emotional disturbance. Lysal still in bed was shown to be not applicable as a criterion of rest. The authors believe that cases of ophthalmic goitre in which the etiology is uncertain should be investigated in order to determine what symptoms are due to thyroid secretion and what are referable to a lowered threshold of emotional activity. Two cases are described in detail, a table of the investigations is published, and the metabolism readings for the group of cases examined are set out in a chart.

#### 178. Streptococci in Scarlet Fever.

C. ZOLLER (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 18th, 1924, p. 1696) states that the American authors Dick and Zingher agree with Borgé's theory (1895) that the specific cause of scarlet fever is a haemolytic streptococcus, hypodermic injections of the dilute streptococcal toxin demonstrating the susceptibility or immunity to scarlet fever. Zoller finds that the exact dilution of the toxin could not be determined by animal experiment, as rabbits react only slightly and guinea-pigs do not react at all. He has given 0.2 c.c.m. hypodermically to various white and coloured patients. Among 125 whites he found 38 "receptives." All of these patients had recovered recently from otitis media, sore throat, rubella, erysipelas, diphtheria, or from non-contagious diseases; the reaction has also been tested in a few healthy persons. It appears to be from twenty-two to twenty-four hours as a small red patch, described as feebly positive, positive, or strongly positive, in proportion to the size and degree of infiltration of the area involved. It disappears in two or three days; in some cases, slight pigmentation persists. Zoller remarks that occasionally there is slight itching at the moment that the reaction occurs, apparently analogous to the pruritus that sometimes accompanies a scarlatinous eruption. After twenty-four hours, when the reaction is fading, it may be restored by rubbing the area with an alcohol-ether mixture. Whatever may be the significance of the reaction, it is often difficult among a rural population to determine certainly who has or has not had scarlet fever. In 3 cases it was ascertained that a second attack occurred in (a) seventeen years, in (b) nine months, and in (c) four months after the original attacks; in (a) and (b) Dick's reaction was negative, in (c) feebly positive. In a case of scarlet fever a positive reaction was observed on the third day, which became negative on the eighth day. It would appear that there is no difference between the strains of scarlatinous streptococci in France and overseas. In 6 patients convalescent from erysipelas, four negative and two definitely positive reactions were obtained: 2 of these patients had received large doses of antistreptococcal serum, but this did not prevent the occurrence of Dick's reaction.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 179. The Diagnosis of Scarlet Fever.

J. COMBY (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 25th, 1924, p. 1723) remarks that the diagnosis of scarlet fever is occasionally very difficult, a point of importance in connexion with the question of recurrence of the disease. Scarlet fever, like rubella, is believed to recur very rarely, but Comby has seen several examples of recurrence. In three cases scarlet fever recurred after intervals of five, six, and ten years. A girl of 18 had had a definite attack at the age of 8. Comby saw her and her brother ten years later; both had a generalized eruption and follicular tonsillitis, and extensive desquamation followed. Comby has also published cases of relapse after two or three weeks, both in scarlet fever and in rubella; he considers that one of the most valuable diagnostic signs is desquamation of the tongue. He describes the cases of twin sisters, aged 8, whose initial symptoms resembled those of scarlet fever so strongly that he treated them as such; however, there was no lingual desquamation, and only slight scaly desquamation of the cheeks—none elsewhere; the disease proved to be rubella. In another case, in a girl of 8, there was moderate fever, sore throat with whitish patches, and a pale, indolent eruption. About the fourteenth or fifteenth day lingual desquamation occurred—the classic “strawberry tongue”—followed by typical “glove-finger” desquamation. The presence or absence of lingual desquamation is, according to Comby, a vital point in the diagnosis of scarlet fever; Hallé maintains, however, that slight or moderate lingual desquamation, complete by the sixth day, is not reliable. He observes also that in malignant scarlet fever the tongue is dry and red, but there is not time for desquamation to occur. Néter states that lingual desquamation, although a valuable sign, does not occur until the end of the first week, and that it is rarely possible for the diagnosis to be made at an earlier date than this.

### 180. Recurrent Tuberculous Meningitis.

C. LOTTI (*Il Policlinico*, Sez. Med., November 1st, 1924, p. 593) records the case of a woman with the following history. At the age of 20 months she had had a febrile attack accompanied by nuchal rigidity and hyperaesthesia. Apart from an attack of menses in the same year she remained in good health until the age of 10 years, when she had a severe attack of meningitis, from which she recovered completely except for dystrophy of the retina and choroid on the right side. After an interval of fifteen years, during which she remained in good health, the meningitis recurred in attacks of more or less intensity at intervals of varying duration, and manifested by symptoms of intracranial hypertension, hemiparesis, and homianesthesia on the left side, and transient nystagmus. This condition persisted for three years. Although tubercle bacilli were not found in the cerebro-spinal fluid and the inoculation of guinea-pigs was negative, Lotti regarded the meningitis as tuberculous, and traced it to caries of the body of a vertebra, for the following reasons. The cerebro-spinal fluid showed all the cytological and clinical features of tuberculous meningitis—namely, slight xanthochromia, considerable excess of albumin with increase of globulin, loss of reducing power, and well developed pleocytosis, with a mixed polymorphonuclear and lymphocytic formula. Syphilis could be excluded, as the Wassermann reaction was negative in the blood and cerebro-spinal fluid. The case resembled that of relapsing tuberculous pleurisy described by Piery in 1910 in its relatively mild character and tendency to recurrence. Relapsing tuberculous meningitis is not exceptional in the adult, as cases have been recorded by Riebold, Perronne, Lutet, and many others. A striking feature, however, in Lotti's case was the absence of any tendency for the disease to progress, although the condition could not be described as cured.

### 181. Atypical Forms of Epidemic Encephalitis.

A. V. NEEL (*Ugeskrift for Læger*, December 18th, 1924, p. 1013) draws attention to the frequency of obscure conditions the relation of which to epidemic encephalitis would not be suspected unless a careful study were made of the history of the case. The development, at a comparatively late stage, of after-effects similar to those following an attack of epidemic encephalitis is significant. In 1923 the author examined forty patients three to six months after they had suffered from one or more attacks of severe hiccups, and in 80 per cent. he was able to demonstrate more or less definite

clinical signs of epidemic encephalitis. The fact that the rise in the number of cases of this disease synchronized with the rise in the number of cases of epidemic hiccups further stressed the likelihood of an etiological connexion between the two. The author publishes details of ten cases observed late in 1924, and of interest because of their suspected relationship to well defined epidemic encephalitis. In two of these cases an attack of persistent hiccups recurred, the interval in one case between the two attacks being about three years, and in the other case almost four years. In both cases there were attacks of giddiness and the ocular symptoms which are common in epidemic encephalitis. In one case there was paresis of the right arm. In a third case there was persistent hiccups day and night for three and a half days, associated with a sensation of feverishness; but there were no signs of coryza, and there was no previous history of hiccups. This patient, who was a man aged 49, had contracted “Influenza” in the summer of 1918, with much drowsiness. At the same time one of the seven children at home also fell ill. Since then he had had disturbances of vision, and Neel believes that ever since the summer of 1918 this patient had been suffering from a mild and abortive form of epidemic encephalitis which, in December, 1924, flared up in the form of epidemic hiccups.

### 182. Anginal Attacks caused by Pain in the Left Arm.

G. D. ARONOWITZ (*Klin. Woch.*, January 15th, 1925, p. 117) records a case which is of much interest, with respect to Mackenzie's views on angina pectoris of the viscerosomatic reflex. A man, aged 29, suffered from a gunshot wound of the left arm and amputation was performed a little above the elbow. Amputation neuromata developed later in the stump, and caused great neuralgic pain. Two neuromata were removed, but a haematoma developed after the operation, and persistent severe pain in the arm followed, with repeated attacks of cardiac pain and other symptoms simulating those of angina pectoris. No signs of heart disease could be detected, but the cardiac region of the chest and the left brachial plexus were hyperaesthetic. After twelve days the haematoma was punctured and blood removed. The anginal attacks and pain ceased, and the patient returned to his occupation. No further anginal attacks have occurred. Since primary cardiac and vascular disease can be excluded, the author considers that this case shows that attacks simulating angina pectoris may develop through severe neuralgic pain in the left brachial plexus (senso-visceral cardiac reflex).

## Surgery.

### 183. Operative Treatment of Cholecystitis.

H. BARDY (*Finska Läkarsällskapets Handlingar*, November-December, 1924, p. 891) has compared the immediate and late after-histories of the patients who were treated in his hospital since 1902 for cholecystitis, and who were given either operative or conservative treatment. Of the total of 223 patients, 105 were operated on, and 118 were given conservative treatment because they were unfit for an operation or refused to submit to it. The ratio of women to men was 179 to 44. Of the 105 patients operated on, 90 were women, and the age of 82 of them was between 31 and 60 years. Jaundice was present in 40 cases and fever in 41. There were 6 deaths following the operation, but it should be noted that in 2 of these cases peritonitis had already developed before an operation was performed. In as many as 96 cases the operation performed was cholecystectomy; in the remaining 9 cases it was cholecystostomy. Only in 9 cases was the operation wound closed at once; in 11 cases the biliary passages were drained, and in 80 cases a cigarette drain was passed down towards the foramen of Winslow. In 93 cases stones were found. Inquiries as to the subsequent fate of these 105 patients were unsuccessful in 16 cases; of the 89 patients who were traced and re-examined 79 had gall stones present at the time of the operation, and of these 79 as many as 76 had remained perfectly well after the operation, except for an occasional slight attack of dyspepsia in some cases after a too-fat meal. Of the remaining 10 patients, in whom gall stones had not been found at the operation, 6 had remained perfectly well after it, and 4 were still subject to nervous disturbances. With regard to the patients given conservative treatment, 75 of the 118 were subsequently traced, and it was found that 49 had suffered from relapses, 3 had died of disease of the biliary system, and 5 had subsequently undergone an

operation. The author concludes from those experiences that operative treatment is the best when cholecystitis is hyperacute, and the biliary colic is complicated by events threatening life. If possible, an operation should be performed in a free interval and not during an acute attack; when the patient is old and weak the advantages of operative and conservative treatment should be very carefully weighed the one against the other.

#### 184. Gastro-duodenal Ulcer.

G. ALBERGO (*Clin. Med. Italiana*, September-October, 1924, p. 106), after a brief historical reference, discusses the etiology and pathogenesis of gastric ulcer. Of the various hypotheses put forward he believes that of auto-digestion comes nearest to the truth. The treatment may be medical or surgical. He thinks that there is no general specific remedy, and that each case must be treated on its merits; one method of treatment (the medico-dietetic) does not exclude the other (surgical). Of the surgical methods the author believes that gastrotomy (partial or subtotal) gives better results than gastro-entrostomy. An appendix of sixty-three references to recent literature on the subject is provided.

#### 185. Injury of the Musculo-spiral Nerve.

W. R. MACAUSLAND and A. R. MACAUSLAND (*Amer. Journ. Med. Sci.*, January, 1925, p. 1) review the literature relating to injuries of the musculo-spiral nerve, and describe three cases that they have themselves encountered of the more severe type of these injuries. They divide the injuries into three groups: those in which the nerve trunk is crushed without damage to the sheath; complete division of the nerve; and loss of power through involvement of the nerve in scar tissue or callus. They emphasize the importance of early recognition and treatment of nerve injuries in connexion with fractures and other severe wounds, since immediate suture of the nerve usually gives rise to very good results. The chances of success appear to be lessened after the occurrence of a long period of paralysis. In some cases simple freeing of the nerve was the only procedure necessary to relieve the condition. When this, or nerve suture, proved to be ineffective, and such procedures as manual stretching, neurotomy, or nerve grafting had failed, tendon transplantation often gave satisfactory results. The authors find that in cases of nerve suture the functioning power developed in the same manner as in spontaneous healing; in secondary suture sensibility returned early. Muscle control usually appeared in the course of two to four months, and was complete in six to nine months, depending upon the site of the nerve injury.

#### 186. Suppurative Arthritis of the Knee-Joint.

H. GAUDIER (*Bull. et Mém. Soc. Nat. de Chir.*, December 27th, 1924, p. 1168) describes a method of treating acute pyogenic infection of the knee-joint. He records the case of a man, aged 35, who was in a graye condition as the result of an injury to the knee ten days previously. The joint was flexed, swollen, and acutely painful; it was therefore opened by dividing the patella transversely. The joint cavity was found full of pus and acutely inflamed; it was washed out with serum and then exposed for six minutes to the ultra-violet rays. The patella was then sutured and the wound closed. The pus was found to contain streptococci. Fourteen further exposures of the knee to the ultra-violet rays followed, one each day, and the patient ultimately recovered with full movements in the joint. Gaudier considers that the light treatment played an important part in the cure of the condition. He further emphasizes the point that antiseptics are usually of no value in these cases when applied by themselves.

#### 187. Auto-transfusion.

L. H. APPLEBY (*Canadian Med. Assoc. Journ.*, January, 1925, p. 36) reports the use of auto-transfusion in nine cases of ruptured ectopic pregnancy, and suggests that this treatment should be equally applicable in many other conditions with extensive haemorrhage into the serous cavities, such as in cases of ruptured spleen, liver, uterus, or lung. He believes that the procedure is comparatively safe, and has not encountered any fatality or unpleasant reaction. His technique is as follows. While the abdomen is being opened an assistant inserts a cannula into a vein in the arm and begins to introduce normal saline solution. Fluid blood in the abdomen is collected, filtered through gauze, moistened with saline solution, and allowed to run into a beaker containing more which the saline is already running into the vein through the cannula. The author's nine patients recovered, and the amount of fluid reintroduced ranged from 160 to 420 c.cm., in addition to about 200 c.cm. used as a vehicle.

## Therapeutics.

#### 188. The Therapeutic Value of Tetrophan.

O. FOERSTER (*Klin. Woch.*, January 8th, 1925, p. 55) records his experience of tetrophan in the treatment of nervous diseases. This drug, introduced into therapeutics by Pohl, is allied to strychnine in its action on animals; it has a marked physiological action, but little toxic effect. The author considers it to be a valuable drug, though its action is only palliative. Since the drug increases the reflexes considerably in animals, Foerster thinks its chief value in therapeutics is in those affections in which the reflexes are lost or diminished. He has found it of most use in tabes dorsalis. The effect of the drug which is of greatest practical importance in this disease is the marked improvement which it produces in the gait, by diminution of the ataxia. As tetrophan excites the sensory centres, it is not surprising that large doses, and long-continued administration, are followed by hyperaesthesia and paraesthesia in this disease. The drug is contraindicated in cases of gastric, laryngeal, bladder, and intestinal crises in tabes. No good results were obtained by the use of the drug in disseminated sclerosis, except in two cases which presented symptoms of cerebellar ataxia; in these it was of distinct service. Good results were obtained also in myasthenia; and in Parkinson's syndrome following encephalitis. The dose of tetrophan recommended by the author is 0.1 gram twice daily in cases of tabes. This dose, he finds, may be continued for weeks or months without bad effects; but if given in doses of 0.2 gram twice daily, toxic symptoms sooner or later occur. In affections other than tabes smaller doses were given. The action of the drug is palliative; when it is discontinued the beneficial effects soon cease.

#### 189. Treatment of Pyelocystitis.

H. F. HELMHOLTZ and FRANCES MILLIKIN (*Amer. Journ. Dis. Children*, December, 1924, p. 700) record a series of cases illustrating the value of hexamile in chronic pyelitis. They conclude that this drug has valuable therapeutic powers apart from its high concentration of formaldehyde. Definite improvement occurred before this concentration reached the point usually deemed essential for good results. The authors further consider that calcium chloride is of considerable value in rendering the urine acid, being better in this respect than hydrochloric acid and benzoic acid. They give doses of 15 to 45 grains of calcium chloride, four times a day at six-hourly intervals. In this way they obtained a hydrogen ion concentration of 5 or lower, which would be effective in inhibiting growth in staphylococcal infections. They further show, from experimental work on rabbits, that alkali administration definitely increases the output of urine.

#### 190. Antispasmodic Treatment of Involuntary Muscle.

BENZYL BENZOATE and "Akineton," the monobenzyl amide of phthalic acid, both exert an inhibitory action on unstripped muscle fibre by virtue of their benzyl radical. M. ROCH and S. KATZENELBOGEN (*Rev. Méd. de la Suisse Romande*, December, 1924, p. 785) have obtained identical results from the exhibition of these two drugs, and since benzyl benzoate has an unpleasant taste and is difficult to administer they now use the latter exclusively, the calcium salt being given in 50 cc. tablets four or five times a day by the mouth, and the sodium salt in 25 per cent. solution hypodermically. The pharmacological action of these drugs is similar to that of papaverine—namely, inhibition of peristalsis, diminution of tone, and relaxation of spasm of unstripped muscle fibre. Like papaverine they affect the muscle cells directly, and not the peripheral nerve terminations. Dilatation of the peripheral blood vessels occurs with fall of blood pressure, but there is no appreciable action on the vasomotor centre, heart, central nervous system, respiration, or kidneys. Benzyl benzoate in doses of 20 to 30 drops in alcoholic solution has been used by several clinicians, quoted by the authors, in a variety of diseases, all of which, however, had this point in common—that there was an exaggerated contraction and spasm of unstripped muscle. Good results have been obtained in such cases as spasm of the intestine, of the biliary ducts, urethra, bladder, sphincters, angiospasm, bronchial asthma, dysmenorrhoea, and in whooping-cough in children, who tolerate the drug well. Considerable improvement in subjective symptoms, such as headache, vertigo, and nervous crises, has been noted in cases of high blood pressure. The authors report favourable results in three groups of cases: (1) Affections of the alimentary tract, such as cardiospasm, dysphagia with aphonia, nervous dyspepsia associated with a sensation of weight and cramp in the epigastrium after food, dyspepsia with abdominal pain, and pyloric spasm with no organic lesion. (2) Such conditions of spasm as asthma, formication, and intermittent claudication of the lower limbs.

(3) Cases of high blood pressure. In this last group the authors found that no improvement was obtained in cases of chronic nephritis with high tension, there was an appreciable fall of pressure in arterio-sclerosis without renal disease, but the best results were obtained in cases of angio-spasm. The authors also quote unfavourable results that have been reported by some observers; but conclude that unsuitable cases were selected for the administration of the drug.

## Ophthalmology.

### 191. Hydatid Cysts of the Orbit.

D. J. WOOD (*Brit. Journ. Ophthalmol.*, January, 1925, p. 4) describes three cases of hydatid cysts of the orbit. These cysts fall into two classes—those situated within the cone of muscles and those without. In the former case the eye is likely to become blind, whereas in the latter this is much less probable. Even when blindness has occurred there are usually no morbid signs to be detected in the fundus. Diagnosis may be very difficult; proptosis with the absence of a palpable tumour, a negative Wassermann reaction, and no signs of inflammation are suggestive if the patient lives in a land, such as South Africa, where hydatid disease occurs. Aspiration may be very helpful in diagnosis. In Wood's three cases operations were performed; in one case the eye was removed, in the others the orbit was explored with success. The exploration was rendered particularly difficult by the intraorbital fat. A striking fact in the two successful cases was the speedy return of vision after the operation, the eyes having been previously blind for four months and six months respectively.

### 192. Epithelial Cells in Conjunctival Infections.

H. J. HOWARD (*Amer. Journ. Ophthalmol.*, December, 1924, p. 909) describes the methods devised and used by Lindner in Vienna for the study of the micro-organisms of the conjunctiva and cornea. He confirms Lindner's conclusions. He finds that certain micro-organisms (*gonococci*, *pneumococci*, *Koeb-Weeks*, *diphtheria*, and *influenza bacilli*) are parasites of the epithelial cells, proliferating on the surface of the cell and drawing nutriment from it. The exotoxins of these bacteria cause dissolution of the intercellular and interlamellar cement substance of the cells, allowing the bacteria to penetrate more deeply. This does not usually happen in the case of the superficial cornified corneal cells, but is the rule with the superficial conjunctival epithelial cells. Epithelial cell phagocytosis and digestion of the parasitic bacteria occur. Leucocyte phagocytosis seems to play no part in the fight between the epithelial cells and the invading bacteria. Certain bacteria have the power of becoming parasites of the cytoplasm of the living epithelial cells which ingest but do not kill them; this accounts for the so-called inclusion bodies. A fact of importance which Howard believes to be definitely established is that the presence of bacteria in smears from the conjunctival secretion, and the result of cultures made from such smears, do not in themselves establish the etiology of an inflammation of the conjunctiva or cornea. He emphasizes the point that it is necessary to take a scraping of the superficial cells, since this is where the infective organisms will be found.

### 193. The Clinical Value of Slit-lamp Findings.

B. GRAVES (*Trans. Ophthalm. Soc.*, vol. xlv, 1924, p. 197), who is carrying on investigations to correlate slit-lamp and histological findings, reports the case of a simple pigmented mole, or innocent melanoma, occurring at the sclero-corneal margin of a boy, aged 10. The greater part of the tumour was composed of round cells arranged in a definitely alveolar manner, the alveoli being irregular in form, with intercommunication of adjacent spaces. The deep aspect of the tumour was sharply defined from the underlying tissues, which were free from infiltration. Graves gives an account of the slit-lamp findings, including the important indication of the absence of cellular infiltration of the surrounding tissues. He draws attention to some new phenomena in slit-lamp examination, including the observation of fluid-containing spaces, the study of the four reflecting anatomical surfaces of the cornea and lens, and the recognition of the epithelial impact line. He acknowledges the assistance afforded by the grant of a science research scholarship by the British Medical Association.

### 194. Defective Vision and Neurosis.

L. K. LUNT and R. A. FOX RIGGS (*Journ. Amer. Med. Assoc.*, December 20th, 1924, p. 1968) draw attention to some functional nervous disorders which are important in ophthalmological examination. Refraction errors, especially when requiring

repeated correction, should give rise to suspicion that some neurasthenic factor may be concerned. Hysterical amblyopia may occur in young girls, aged about 12, in early school life, and involve functional contraction of the field of vision. At about 20 in both sexes some difficulty in the use of the eyes is not infrequently reported and found to be associated with nervous symptoms. Muscular anomalies which imply errors of convergence may be more important than refractive errors. The authors urge that in such cases particular attention should be paid to observing whether other evidence of neurasthenia is obtainable, in order that correct treatment may be started; they utter a warning against the prescription of glasses for persons below the age of 20 without great care being taken to exclude such existence of neurosis. They think that a conservative estimate of patients so affected amounts to 20 to 30 per cent. of applicants for ophthalmological treatment, and that, therefore, more attention should be paid to this condition.

## Obstetrics and Gynaecology.

### 195. Diabetes and Pregnancy.

A. SPRINGER (*Zentralbl. f. Gynäk.*, November 29th, 1924, p. 2642) summarizes the literature relating to diabetes in pregnancy. He finds that conception only occurs in about 5 per cent. of diabetic women, because (1) the disease is rare during the fertile years of life, and when it does occur is rapidly fatal; (2) the disturbances of genital function due to diabetic amenorrhoea, dysmenorrhoea, atrophy of the genitalia, premature menopause, and pruritus are unfavourable to the occurrence of pregnancy. When it does occur it is followed in 50 per cent. of cases by premature confluence or stillbirths; but in the other 50 per cent. of cases the infants are remarkably well developed. Gigantism may occur. Figures are given to show that the outlook is bad for the mother chiefly because diabetes in young patients is more rapidly fatal, and for the child because difficulties in delivery frequently occur. The author holds that diabetes is an etiological factor in cases of gigantism; but admits the difficulty of explaining why the presence of sugar in the maternal blood should in some cases produce abortion and in others increased growth. He suggests that when the foetus has a well functioning pancreas of its own the rich sugar-containing blood is a stimulus to active growth, but that when the foetal pancreatic secretion is faulty or absent then the high maternal blood sugar is not only useless but is directly inhibitory to growth. In the first type of case one would expect the progress of the disease to be checked during pregnancy, and in the second type to be accelerated. Experiments on animals gave the following results. Extirpation of the pancreas during the last weeks of pregnancy did not result in symptoms of diabetes, though these appeared promptly in the puerperium, showing that the foetal pancreatic secretion could influence the maternal tissues. Another experiment on guinea-pigs demonstrated that the foetal pancreatic secretion was independent of the maternal—that the blood sugar in the foetus was at first very low and only approximated the maternal figure towards the end of pregnancy. Springer concludes that from the practitioner's point of view it must be borne in mind (1) that a diabetic mother may have an abnormally large child, and that difficulties may occur during labour, which should therefore be induced at a suitable time—Caesarean section is not advisable; (2) that when gigantism is diagnosed the possibility of diabetes in the mother should be thought of, and not be dismissed even if an examination of the urine during the puerperium be negative.

### 196. Gas Gangrene of the Uterus.

W. LEHMANN and E. FRAENKEL (*Arch. f. Gynäk.*, October 13th, 1924, p. 692) state that gas gangrene of the uterus, due to infection by Fraenkel's bacillus, is almost invariably accompanied by extensive haemolytic changes leading to yellowish-brown pigmentation of the skin, a burgundy tinting of the serum, and dark red colouring of the urine; haemoglobin, methaemoglobin, and haematin are to be found in both blood and urine. At the same time the patient, whose malady nearly always follows an attempt to induce abortion mechanically, manifests considerable cyanosis and dyspnoea. The prognosis is extremely grave, but Brütt has recorded two recoveries after hysterectomy. The authors point out that it is of great importance to ascertain, if possible, by clinical examination whether the infection has spread from the endometrium to the myometrium. Haemolytic phenomena with colouring of the skin, serum, and urine may occasionally occur in cases without this passage, and such cases may eventually do well. As an example they record two haemolytic cases in which Fraenkel's bacillus

was present in the blood and urine; bimanual examination failed to reveal gas cysts in the uterus, and the patients recovered after curtting. In a third case, which showed the caution necessary in prognosis, the initial findings were similar, but an attempt to curette brought to light two uterine perforations, and the gas bacillus was found in the peritoneal exudate at autopsy. In a fourth case the haemolytic manifestations cleared up after curtting, but the patient died eventually after some days' anuria. Diagnosis of this infection is most speedily made by finding the gas bacillus in the cervical fluid and the urinary sediment; blood cultures are not always positive. Lehmann and Fraenkel state that the bacillus was found in the cervix in no fewer than 106 of 580 abortions treated in a Hamburg clinic during 1923; in none of these cases, however, did the infection pass to the myometrium or parametrial vessels. In some of these cases Fraenkel's bacillus was recovered from the blood stream, but even then the occurrence of a rigor was exceptional.

#### 197. The Menopause and Arthritis.

R. L. CECIL and B. H. ARCHER (*Journ. Amer. Med. Assoc.*, January 10th, 1925, p. 75) consider that there is a delusio clinical syndrome which may be termed "arthritis of the menopause." This is described as being a chronic poly-arthritis of obese middle-aged women, occurring at, or soon after, the menopause, and characterized by persistent stiffness and pain in the joints. It appears to be non-infectious in origin, and to be dependent on some endocrine condition which has not yet been determined. In their series of 60 cases the average age was 52½ years—the youngest patient was 42 and the oldest 66. Married women supplied 90 per cent. of the cases. No typical examples of this form of arthritis were encountered in men, and Cecil and Archer believe that the symptom-complex of arthritis in middle-aged men differs considerably from that associated with arthritis of the menopause. The authors add that the disease runs a mild chronic course, and that under treatment with iodides, physiotherapy, and a low caloric diet the majority of the patients were definitely benefited, though none were completely cured.

### Pathology.

#### 198. The Pathogenesis of Tetany.

O. TEZNER (*Monats. f. Kinderheilk.*, December, 1924, p. 207) discusses the pathogenesis of the infantile and hyperpuoic forms of tetany. The theory of excessive alkalinity of the blood and consequent deionization of the blood calcium has stimulated much experimental work, but the experimental findings have been contradictory, and the fact, which is emerging from them now is that alkalosis is not the all-sufficient cause of every form of tetany. It is known that a deficiency of calcium produces a hyperexcitability of the nervous system, and that in most cases of tetany the total blood calcium is reduced; the supporters of the theory of alkalosis say that, as it is only the ionized calcium that is active, it is sufficient to correct the alkalinity, because in that way more calcium will be ionized and so rendered effective. Tezner, in a series of thirteen cases, has endeavoured to compare the effects of (1) giving ammonium chloride only, thus correcting any alkalosis and not increasing the total calcium; and (2) giving calcium only and in a non-ionizable form (calcium lactate), leaving the alkalinity of the blood unchanged. The ammonium chloride and calcium lactate were given at different times to the same children, and their effect on the illness was judged by the symptoms, the disappearance or persistence of Chvostek's, Hoffmann's, and Trousseau's signs, and the electrical excitability of the muscles. It was found that ammonium chloride acted more quickly and energetically, but that calcium lactate also had a pronounced beneficial effect, and cured some cases which did not respond to ammonium chloride. This effect of calcium lactate suggests that the administration of any form of calcium leads to an increase in the amount of ionized calcium in the blood even when the pH is unchanged; it follows that the non-ionized portion of the blood calcium has an effect in preventing tetany. The pH of the blood was estimated in every case, but it was found that there was no constant difference between its value in children with tetany and its value in healthy children; neither did the total acidity of the urine show any constant change. Tezner considers that all these findings go to show that alkalosis cannot at any rate be the only factor in causing infantile tetany. As regards hyperpuoic tetany, it was from the investigation of this condition that the theory of alkalosis be brought about in the same person by the same degree of

alkalosis, however produced. The author, by forced breathing for twenty minutes, caused tetany in himself; a sample of blood taken then was found to have a pH of 7.49. On another occasion the pH was raised to 7.51 by the intravenous injection of 500 c.c.m. of a 4 per cent. solution of sodium bicarbonate, but no signs of tetany occurred. Alkalosis cannot therefore be the only factor in causing hyperpuoic tetany. Tezner suggests that the hypertonic state of the blood following the injection of such a strong solution may have had a counteracting effect.

#### 199. Serological Relations between Streptococci and Pneumococci.

In a previous paper C. H. HITCHCOCK, using the precipitin test, had reported that the haemolytic streptococci, the non-haemolytic streptococci, and the pneumococci formed three serologically distinct and non-related groups; it was further ascertained that whereas the haemolytic streptococci formed a practically homogeneous group, the non-haemolytic streptococci were decidedly heterogeneous. He has now (*Journ. Exper. Med.*, January, 1925, p. 13) continued his study, replacing, however, the precipitin by the complement fixation test. A series of 3 haemolytic streptococci, of 16 non-haemolytic streptococci, and of 14 pneumococci, mostly isolated from cases of human disease, was collected; against each strain an antiserum was prepared by injecting the killed organisms intravenously into rabbits. The bacterial antigens for the complement fixation reaction were prepared by centrifuging the organisms in a twenty-four-hour glucose broth culture, washing them in saline, drying them *in vacuo* over phosphoric anhydride, dissolving the resulting powder in 4 per cent. antiformalin, neutralizing with acid, and adding sodium thiosulphate to remove the excess of chlorides. For the actual test the usual rabbit-sheep combination was used, the complement being kept constant and the immune serum varied. The results showed that each of the three serums prepared against the haemolytic streptococci was able to fix complement in the presence of antigens of all groups. The non-haemolytic streptococcal serums fell roughly into two main groups: one of these reacted with its own group of non-haemolytic streptococci and with the haemolytic streptococci; the other reacted with its own group and with the pneumococci. With regard to the pneumococcal serums they reacted fairly well with all types of pneumococci, though there was a rather closer relation between the Type IV and the Type II strains than between the others, and with one group of the non-haemolytic group streptococci. From these results it appears that the non-haemolytic streptococci may be divided into two groups—one related to the haemolytic streptococci and one related to the pneumococci. These relations are not associated with the precipitable substances, but are probably dependent on the properties of the protein or lipid fraction of the bacterial cell.

#### 200. The Leucocytes in Osteitis Deformans.

A. PINEX (*Journ. Path. and Bact.*, January, 1925, p. 122) has examined the blood of five cases of osteitis deformans in order to ascertain whether any changes are present as a result of lesions in the bone marrow. In none of the cases was there any anaemia, nor was there any alteration in the total number of circulating leucocytes. A differential count of the white cells showed an increase in the basophil cells, which varied in the different cases from 1.7 to 4 per cent., and an increase in the eosinophils, which varied from 6.8 to 10 per cent. The other cells were present in more or less normal proportions.

#### 201. The Cerebro-spinal Fluid in Tetanus.

J. SABRAZÉS, P. F. SAINTE-MARIE, and R. DE GRAILLY (*C. R. Soc. de Biologie*, December 27th, 1924, p. 1407) have searched through the notes of patients admitted to hospital during the years 1910-24 suffering from tetanus in order to ascertain the reaction of the cerebro-spinal fluid in this disease. Altogether they have collected 28 cases suitable for this purpose. Briefly they find that the albumin content is only slightly raised, if at all; that the urea is practically normal; that there is no increase in the number of cells; that the few cells found are all lymphocytes; and finally—the sole definite abnormality—that there is a rise in the percentage of glucose. Since, however, this estimation was made in only five cases, of the series, and as one of these five had previously received an intraspinal injection of antitetanic serum, it was doubtful whether this rise was definitely demonstrated. The authors consider that it is probably related to the excessive increase in the temperature of the patient, as Mestrozat has found that hyperthermia in general causes a rise in the glucose content of the fluid. From a diagnostic point of view they consider that the absence of increase in urea might serve to distinguish tetanus from convulsive uraemia resembling tetanus.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 202. Congenital Achondroplasia.

CASES in which the typical features of achondroplasia—namely, dwarfism, macrocephaly, disproportion in the length of the limbs, trident hand, lordosis, sinking of the bridge of the nose—are only present in a slight degree are designated "hypochondroplasia" by A. LÉRY and Mlle LIXOSSIER (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, January 1st, 1925, p. 1780). They describe the condition in a mother and daughter, and say that these cases can readily be distinguished from cases of rickets by the symmetrical nature of the deformities and the absence of spinal distortion. The daughter, aged 21, had suffered from violent paroxysmal headaches for five years. Her condition was not immediately diagnosed, for, though she was only 4 ft. 11 in. in height, her trunk and limbs were well proportioned. She had lordosis, with a prominent abdomen, her nose was depressed at the root, and her head was 23 inches in circumference. Her fingers were podgy and clubbed, but did not present the characteristic trident formation. The fourth metacarpal was almost half an inch shorter than the adjoining ones, with consequent apparent shortening of the ring finger. The fourth metatarsal showed a similar deformity, and hallux valgus was also noted. In spite of a negative Wassermann reaction and absence of a family history suggestive of syphilis, antisyphilitic treatment was tried, to which the headaches rapidly yielded. The mother, 4 ft. 10 in. in height, presented the same deformities as her daughter, as did also the mother's father. The husband was of normal stature and a second girl was normal.

### 203. Acute Pulmonary Oedema Associated with Epilepsy.

L. LANGERON (*Presse Méd.*, January 17th, 1925, p. 65) reports an unusual case of true acute pulmonary oedema immediately following attacks of epilepsy. The author observes that in this case he was dealing with a true acute oedema and not merely the cyanosis and frothy expectoration which often follows an epileptic fit, and is of naso-pharyngeal or glossal origin. The patient, a woman aged 42, had been married twice and showed signs of syphilis. In early life she suffered from chorea and one attack of rheumatism which left no trace of cardiac affection. At 20 she had a febrile attack which may have been typhoid fever, after which the chorea ceased, but was followed every month by vague nervous symptoms. After an attack of mumps, two years ago, she developed regular epileptic fits; after the fit she became very cyanosed, intensely dyspnoeic, and brought up quantities of frothy blood-stained sputum, while râles were heard throughout the chest. Relief followed copious bleeding. A similar attack of oedema was noted after another epileptic fit. Cases of true pulmonary oedema are rare—the author has only been able to collect 17 (10 women, 7 men), of whom 9 died. With one exception there was no cardiac or renal affection; in another case the thymus was enlarged. After discussing the pathogeny he suggests that his case was a visceral epilepsy comparable with migraine, angina, or sweating, and due to a spread of the irritation in the motor cortex to the bulbocordular areas.

### 204. The Stokes-Adams Syndrome and Neosalvarsan Treatment.

GEORGES BICKEL (*Arch. des Mal. du Cœur, des Vaisseaux et du Sang*, January, 1925, p. 39) combats the "erroneous theory" that the majority of cases of complete heart-block are due to syphilis; he remarks that the routine employment of arsenobenzol in these cases is not free from danger, although it may produce good results in a small number of cases. Bickel insists that the Stokes-Adams syndrome is in no sense a definite entity; the same clinical result may be determined by a series of different processes, among which syphilis must take a far less important position than that which it has occupied during the last twenty years. Bickel records the following case as an indication of the danger of prescribing "test courses" of neosalvarsan when no clinical or pathological evidence of syphilis has been found. The patient, a very obese but otherwise healthy man, aged 48, had been subject for two years to frequent transient syncope attacks, sometimes preceded by dyspnoea and retrosternal pain. There was marked bradycardia, and the pulse rate was only about 30 a minute, regular and strong. The radial pulses were synchronous and the venous pulse was three or four times as rapid as that of the arteries. The systolic

blood pressure was 180 mm. and the diastolic was 70 mm. Electro-cardiograms and tracings showed complete auriculo-ventricular dissociation. In spite of the absence of any evidence of syphilis, a series of injections of neosalvarsan was given, the total quantity of the drug injected being 4.95 grams. After the third injection there was a serious aggravation of bradycardia, the pulse rate falling to 16-18 a minute, this being accompanied by transitory attacks of vertigo and grave malaise. In spite of further injections there was no improvement; the patient was discharged after three months' treatment, and was sent into the country. The attacks of syncope persisted, and he died suddenly a few weeks later. Bickel discusses the electro-cardiograms and the features of the case in detail, pointing out that the aggravation of symptoms cannot be regarded as a form of Herxholmer's reaction; if it were, further treatment would have produced improvement. The syndrome would appear to be produced by fatty infiltration of the heart, due to generalized obesity. Several authors have recorded severe damage to the bundle of His resulting from this cause; moreover, the bundle of His is extremely sensitive to toxic agents of all kinds. It would appear that neosalvarsan, acting on a damaged myocardium, can derange the function of the auriculo-ventricular bundle. It has long been known (Ehrlich, Martins) that salvarsan and its derivatives must not be administered to patients suffering from heart disease without great care. Bickel, while fully convinced of the value of arsenobenzol in many syphilitic cases of heart disease, records this case as an instance of the failure of a very valuable remedy.

### 205. Epidemic Dropsy and Beri-beri.

H. W. ACTON and R. N. CHOPRA (*Indian Med. Gazette*, January, 1925, p. 1) conclude that epidemic dropsy and beri-beri are different clinical aspects of a toxic syndrome caused, in the vast majority of instances, by the ingestion of poisonous bases found in rice. Similar poisons, however, may occur in tinned foods and dried fish. The disease in the rice is caused by a spore-forming protozoic bacillus, and the differences in the signs of the two diseases are due to its action upon two different grades of rice. Acton and Chopra find that the poisons in the rice causing epidemic dropsy are water-soluble, while the neurotoxin causing beri-beri is soluble in alcohol only. Individual susceptibility is important when the amount of ingested poison is small, and suprarenal or thyroid insufficiency increases the susceptibility. The authors add that rice polishings contain bases antagonistic to the bases in diseased rice. Bacterial invasion of the grain is prevented by the pericarp and by the protective layer of bacteria living under it. They conclude that polished parboiled rice is the most dangerous, and can only be made innocuous by preservatives and proper storage. Intramuscular injections of adrenalin, 2 minims twice a day, relieves the oedema by diminishing cell permeability; it also antagonizes the action of the water-soluble bases.

## Surgery.

### 206. Thyroglossal Cysts and Fistulae.

H. BAILEY (*British Journ. Surg.*, January, 1925, p. 579) considers the surgical aspects of a series of thyroglossal cysts and fistulae collected from the records of the London Hospital. He states that the diagnosis of a cyst is usually simple except when inflamed; it is then liable to be taken for a tuberculous gland. A useful sign is that a cyst moves upwards on fully protruding the tongue. Rarely it may be the only thyroid tissue present; this must be remembered in considering its removal. The commonest site is the subhyoid, and the cyst may disappear behind the hyoid bone when the patient swallows. Thyroglossal cysts occur most commonly in babies, while branchial cysts generally appear in the second decade of life. Thyroglossal fistulae are said to be rarely if ever congenital, and are usually the result of rupture of a thyroglossal cyst. Suppuration in a cyst plays the chief part in the formation of a fistula. The secretion from a fistula varies in amount: it may be thin, watery, and copious, whilst in other cases it is intermittent. The fistula is often below the cricoid cartilage, and is usually surrounded by scar-like tissue due to uneven growth of the tract and the rest of the neck. Treatment, unless complete is apt to be followed by recurrence, and it is necessary to extirpate all the cysts and every vestige of the tract. The difficult

part of the operation is near the hyoid bone. Sistrunk advises operation by a transverso incision: the central portion of the hyoid bone is removed and the tissues round the tract are "eored out" up to the foramen caecum of the tongue. This dissection removes all the tract completely.

207.

**Pseudo-coxalgia.**

T. P. NOBLE (*Journ. Bone and Joint Surg.*, January, 1925, p. 70) remarks that Legg, who first described pseudo-coxalgia in 1909, regarded trauma as the etiological factor. The disease appears to be by no means rare, and is usually unilateral. Most cases appear during the second half of the first decade of life. The onset of the disease is insidious, and a limp is the first symptom, though, as a rule, there is no pain. Limitation of abduction and internal rotation is found at the hip-joint, whilst in some cases all movements are restricted owing to nunsular spasm. A slight degree of real shortening is usually present, and minor degrees of flexion and adduction appear; the great trochanter becomes elevated above Néaton's line and appears broader than normal. Wasting of the hip muscles is usually present, and Trendelenburg's sign is commonly found. Fragmentation occurs during the course of the disease, and the head of the femur usually breaks up into three pieces. Later the head regenerates, and becomes flattened and enlarged. Osteoarthritic changes are common in later life. There are three hypotheses as to the causation of the disease. Some believe it to be a congenital malformation of the head, others regard it as an infectious condition of haematogenous origin, whilst the traumatic hypothesis has much to support it; with this latter may be associated a congenital weakness of the epiphyseal line. The condition tends to undergo spontaneous cure, and treatment by fixation in a spica cast in slight abduction for six months appears to be all that is necessary.

208.

**Acute Pancreatitis.**

L. ARNSPERGER (*Deut. Zeit. f. Chir.*, December, 1924, p. 189) records his observations on 20 cases of acute pancreatitis which had been treated at St. Vincent's Hospital in Karlsruhe since 1920. Eleven were examples of acute pancreatitis or necrosis of the pancreas, of which 5 recovered and 6 died; 3 were cases of subacute pancreatitis and pancreatic abscess, all of which recovered after operation; 4 were cases of fat necrosis in the abdominal cavity without obvious acute pancreatitis, all of which also recovered after operation; 2 were cases of acute pancreatitis which recovered without operation. Of the 18 cases in which operation was performed 6 died—a mortality of 33 per cent. The best results were obtained by early operation, as had been emphasized by previous observers. The prognosis is also favourable even in late cases in which there is an encapsulated peripancratic abscess. The prognosis is worst in cases in the intermediate stage between intoxication and peritonitis. Three of Arnsperger's cases, however, which belonged to this group, were saved by operation. Arnsperger maintains that acute pancreatitis is no longer a hopeless disease, but that, by early operation and suitable technique, as good results can be obtained as in operations on other severe abdominal affections.

209.

**Surgical Treatment of Thyroid Disease.**

T. L. DEAVOR (*Amer. Journ. of Surg.*, December, 1924, p. 296) considers that the lowest possible death rate in thyroid surgery may be attained only by adhering to three main principles. These are: the preliminary preparation of the patient and selection of the proper time to operate, careful anaesthesia with control of haemorrhage, and after-care. The critical time is the first twelve hours; patients who survive this period generally recover. A bloodless operation should be the objective, since many accidents are due to excessive loss of blood. Deavor finds that all toxic cases do better during the cooler periods of the year. Morphine may be administered after the operation and water is given freely from the start. Signs of toxæmia are treated by ice-bags applied to both sides of the lower extremities, the front and sides of the abdomen, the forehead, vertex, and back of the neck; the good effect of cold in these cases is often most striking. The use of iodine in exophthalmic cases was found most valuable, particularly when toxæmia was marked. Drainage must always be free, especially in toxic and exophthalmic cases, and retained serum allowed to escape. Collapse of the trachea and grave secondary haemorrhage are the chief tragedies of thyroid surgery. The author adds that if haemorrhage produces cyanosis the wound must be opened up and the bleeding point ligatured. He considers that the advanced exophthalmic patients with fixed complications cannot be completely cured. Every case must be seen under observation till the best possible results have been reached.

436 B

**Therapeutics.****210. Gentian Violet in Subacute Infective Endocarditis.**

R. H. MAJOR (*Journ. Amer. Med. Assoc.*, January 24th, 1925, p. 278) reports a case of recovery from subacute infective endocarditis following intravenous injection of gentian violet. The patient, a woman aged 25, was very anaemic, the red corpuscle count being 3,320,000 per c.mm., and the white corpuscle count 3,650; the temperature was 100°F., and a non-haemolytic streptococcus of the *S. viridans* type was recovered in a pure culture. The temperature fell to normal after the intravenous injection of 5 mg. of gentian violet per kilogram of body weight, in a 1 in 5:0 aqueous solution. The blood culture subsequently was found to be sterile, and a second injection of gentian violet was given forty-eight hours later. In all, four intravenous injections were given, and no blood cultures after the beginning of treatment contained streptococci. The patient was discharged much improved: the red blood corpuscles had increased to 4,500,000 per c.mm., and the white corpuscles to 7,000 per c.mm. Seven months after discharge from hospital the patient was in good health, although a loud systolic murmur was still audible at the cardiac apex. During one of the injections the gentian violet was extravasated into the tissues and set up a necrosis with sloughing, which caused considerable discomfort to the patient; this cleared up, however, without any severe complications. Major suggests that the success in his case might well induce the further trial of gentian violet in patients with a more malignant type of the disease.

**211. Intracardiac Injections of Adrenaline in Heart Failure.**

P. MASOTTI (*Il Policlinico*, January 5th, 1925, p. 9) reports a case of heart failure during spinal anaesthesia cured by intracardiac injection of adrenaline. The patient, 63 years old, suffered from strangulated hernia. Spinal anaesthesia was induced with 8 cc. novocain and 1 c.cm. adrenaline (1 in 1,000). Heart failure occurred at the beginning of the operation and was not relieved by caffeine and other injections, nor by inhalation of oxygen and artificial respiration. As the patient became worse 10 c.cm. of 1 in 1,000 adrenaline was injected into the left ventricle at the level of the fourth intercostal space. As the needle was observed to oscillate almost immediately, it was removed and artificial respiration resumed. Twenty minutes after the adrenaline injection the patient was so much better that it was possible to complete the operation, and the subsequent post-operation course was normal. Before injection of adrenaline the pulse and cardiac beat were imperceptible.

212.

**Insulin in Chronic Rheumatism.**

LÉVY-FRANCKEL, JUSTER, and LACROIX (*Bull. Soc. de Thé.*, December 10th, 1924, p. 301) have treated five cases of chronic rheumatism by injections of insulin with encouraging results, and record in detail the histories of three cases. The first was in a woman, aged 40, suffering from psoriasis, and chronic rheumatism of the ankles, wrists, and metacarpophalangeal joints; the second was an example of morbus coxae scilicet in a man, aged 56; and the third one of vertebral rheumatism in a man of 54. In each case the injection of insulin had a favourable effect on the pain and loss of power. But whereas in the first patient the effect was only transient, in the third case the improvement was sufficiently pronounced to be regarded as a cure. Without advancing any hypothesis to explain the action of insulin in these cases, the authors remark that the occurrence of chronic rheumatism has been attributed by some authorities to disturbance of certain endocrine glands, especially the thyroid, while others regard a tropho-neurotic origin as more probable. None of the patients was diabetic, so that the blood sugar was not estimated.

213.

**Stovarsol in Yaws and Protozoal Diseases.**

CH. MASSIAS (*Gaz. Hebdom. des Sci. Méd. de Bordeaux*, January 11th, 1925, p. 21) states that stovarsol ("190" Fournier) has given remarkable results in the prophylaxis of syphilis and in the cure of experimental syphilis in the rabbit (Lévaditi and Navarro-Martin). When given by the mouth to rabbits, monkeys, or men it is reported to be quickly efficacious and less toxic than "606" or "914." Lévaditi, Navarro-Martin, and A. Marie found that administration of 2 to 4 grams to a man from two and a half to five hours after "massive" inoculation with syphilitic virus prevented infection. L. Fournier and Guénou gave daily doses of 1 to 1.5 grams (total quantity = 4 to 7 grams) to women definitely infected by their husbands; general infection has been prevented nearly three weeks after intercourse. L. Fournier, R. Dupétié, and J. Sabrazès have obtained rapid improvement in cases of

(a) secondary syphilis, (b) infantile congenital syphilis, and (c) gumma. Sézary and Pomaret advise, however, that novarsenobenzol and bismuth should not be abandoned in favour of stovarsol, as their action persists for a longer period; stovarsol had no effect on the Wassermann reaction. Massias has had remarkable success in the treatment of yaws among the scattered aborigines of Cochín-Chilua. These people will not submit to intravenous medication, nor will they enter a hospital, but they return willingly for further administration of stovarsol. Massias gives large doses in tablet form—for example, to adults 1 gram per diem for three or four days, or even larger doses when the granulomata are very numerous. To children of 10 to 15 years Massias gives half the adult dose, and to younger children proportionately smaller doses. Stovarsol was found to be well tolerated; no digestive disturbances occurred. The effect was rapid; the lesions began to dry up on the third day, and clearing occurred in from ten to fifteen days. Visceral leishmaniasis has not been observed. Massias has obtained good results from giving stovarsol in amoebic dysentery (two or three tablets every day for four or five days, then one every two days for several weeks). Marchoux, Cado, Garib, and Pontanel recorded similar results (1924), and Delanoe of Morocco confirmed this. Garin and Massias have found stovarsol efficacious in lamblolosis and trichomoniasis.

## Diseases of Children.

### 215. Post-operative Acidosis in Children.

P. C. JEANS and K. H. TALLERMAN (*Brit. Journ. Child. Dis.*, October-December, 1924, p. 268) record their observations on fourteen cases of post-operative acidosis in children. The blood and urine were examined before and after operation, and those substances which might be causative factors were estimated. It was found that the lowering of the alkali reserve was due in but small measure to acetone bodies or to lactic acid accumulation. Phosphate retention was obviously not the cause of any acidosis that might exist. In fact phosphate excretion constituted a compensatory mechanism, the phosphates of the blood falling with a lowered alkali reserve, and the phosphate excretion being increased coincidentally. The organic acids excreted increased, and in those cases showing a more marked lowering of the blood  $\text{CO}_2$  were in excess of both acetone bodies and lactic acid. It was therefore presumed that some as yet unidentified factor was responsible for the lowered alkali reserve. The fall of the  $\text{CO}_2$  appeared proportional to the drop in blood pressure. It was observed also that qualitative tests for acetone bodies in the urine gave but a poor indication of the degree of acidosis present if compared with the variation in alkali reserve.

### 215. Epidemic Encephalitis in Infancy.

C. DE LANGE (*Nederl. Tijdschr. v. Geneesk.*, November 29th, 1924, p. 2696), who records two new cases of infantile encephalitis with a review of the literature, remarks that one of the peculiarities of infancy is that cerebral symptoms may occur in all infections and intoxications at this age. As an acute attack of epidemic encephalitis in young children is accompanied by convulsions, tonic contractions, motor restlessness or apathy, unconsciousness, vomiting, and fever, which do not form a characteristic group of symptoms, de Lange thinks that it may be assumed with great probability that a number of cases pass unrecognized, while, on the other hand, it is likely that an incorrect diagnosis of epidemic encephalitis is often made in young children. De Lange's first case was an infant aged 13 months, who in addition to lethargy, myoclonic movements, and exaggeration of the reflexes, showed a remarkable pallor, probably due to changes in the sympathetic centres, and an insatiable appetite, which was attributed to a process in the hypothalamus. A complete change in the child's character also took place. The second case, which occurred in a child of 7 months, was characterized by convulsions, exophthalmos, intermittent rigidity, exaggerated reflexes, bulimia, and a respiratory syndrome resembling whooping-cough. Finally, complete recovery took place.

### 216. Tuberculin Tests in Children.

H. SÖDERSTRÖM (*Finska Läkaresällskapets Handlingar*, November-December, 1924, p. 879) reviews his experiences of von Pirquet tests in children admitted to his hospital in the period 1914-23. Undiluted old tuberculin was used, and altogether 1,476 children up to the age of 10 years were tested. Only 23 per cent. of the children in the first year of life gave a positive reaction, whereas this was obtained in 63.6 per cent. of the children in the tenth year. A positive reaction was obtained in 37.2 per cent. of all the children.

When the children who showed no clinical sign of tuberculosis were grouped by themselves it was found that in this group a positive reaction was obtained only in 21 per cent.; the reaction was positive in 7 per cent. of the children in the youngest group, and in 53 per cent. of the children in the age group 8-10 years. All the children with scrofula gave a positive reaction, and 93 per cent. of the children suffering from idiopathic exudative pleurisy—suggesting that this form of pleurisy should be regarded as a manifestation of tuberculosis. Of the 134 children suffering from pulmonary tuberculosis 10 gave a negative reaction, and 5 of these 10 were less than 6 months old. Among the 66 cases of tuberculous meningitis and miliary tuberculosis there were 12 giving a negative reaction. Of the 285 children showing definite or suspicious signs of tuberculosis only 9.1 per cent. failed to give a positive reaction. The author concludes that his findings are confirmatory of earlier observations in this field, and that they show only too plainly how saturated with tuberculosis are the working classes of Helsingfors.

### 217. Enteric Fever in Children.

H. BISCHOFF (*Arch. f. Kinderheilk.*, December 24th, 1924, p. 83) reviews the literature, and records his observations on 100 cases of typhoid fever in children at the Rostock University Children's Clinic, his conclusions being as follows: (1) The disease occurred chiefly in the summer and autumn, its curve corresponding with that of infantile mortality. (2) The incidence rose with advance in age, 11 per cent. of the cases occurring in the first year, 22 per cent. in the second year, 33 per cent. in young school children, and 34 per cent. in older children. (3) The average mortality was 10 per cent., but was higher in the female sex (14 per cent.) than in the male (6 per cent.). (4) The most important diagnostic symptoms were enlargement of the spleen (44 per cent.), rose spots (63 per cent.), Widal's reaction (88 per cent.), diazo-reaction (73.4 per cent.), presence of typhoid bacilli in the blood (71.8 per cent.), leucopenia (71 per cent.), diarrhoea (52 per cent.), and typical temperature in only 17 per cent. (5) The course of the disease was mild in 38 per cent., moderately severe in 20 per cent., and severe in 20 per cent., the latter being mainly cases complicated by bronchopneumonia, pleurisy, or relapses. (6) The duration of the disease ranged between two and six weeks. Relapses occurred in 8 per cent. One child had four relapses. (7) Bacteriological examination of the stools and urine was rarely positive, the bacilli being found in the stools in only 13 per cent., and in the urine in 2.3 per cent. (8) Treatment was mainly expectant and dietetic. The course of two cases in which vaccine therapy was employed did not differ from that of the others.

## Obstetrics and Gynaecology.

### 218. Carbohydrate Metabolism during Pregnancy.

H. EHRENFEST (*Amer. Journ. Obstet. and Gynecol.*, December, 1924, p. 685) reviews the contributions during the last five years to our knowledge of the modifications of carbohydrate metabolism in pregnancy. With regard to the fairly common disturbance at this time—namely, glycosuria after administration during fasting of 100 grams of glucose, or after small injections of adrenaline or phloridzin—he draws the following conclusions. The condition is not a renal diabetes or glycosuria, for (1) although it appears with a blood sugar concentration which may be as low as 0.082, and has an average level of 0.141, it is preceded by hyperglycaemia; (2) altered endocrine and nervous conditions are present during pregnancy, and the absence of such, as well as of toxic influences, is an essential feature of renal diabetes as clinically understood; (3) the pregnancy glycosurias are not lasting, but take a transient course after artificial provocation. It may not correctly be called an alimentary glycosuria, because this term denotes a condition associated with diminished ability to metabolize carbohydrates, whereas in pregnancy this ability is physiologically increased. Pregnancy glycosuria shows weakness in sugar metabolism only in a lowered ability to deal with one large ingested dose of glucose, laevulose, or even starch. Ehrenfest regards pregnancy glycosuria as due to a lowered renal threshold required as a protective measure in face of greatly accelerated sugar mobilization due to foetal needs. Endocrine changes noted during pregnancy—namely, increased activity of thyroid, adrenals, and the pituitary body—are of a nature to indicate hyperactivity in sugar assimilation. In pregnancy in women whose pancreatic (insular) function before conception is only barely sufficient, or is defective, pregnancy with its changes in sugar metabolism and endocrine function, and with its associated toxic conditions, may lead to a true diabetes. It seems probable that, as in a case of this kind recorded by the author, the use of insulin will eliminate the consequent danger to both mother

and child. Ehrenfest utters a word of caution with regard to the alimentary test. Since one large load of glucose may start a continued glycosuria, transforming a potential into a true diabetes, it is dangerous and reprehensible to give 100 or 200 grams of glucose in the fasting condition unless a preliminary determination has been made of the blood sugar during fasting.

#### 219. Cerebral Metastases in Chorion-epithelioma.

J. S. GREEN (*Med. Journ. of Australia*, November, 1924, p. 498) reports a case of cerebral metastases occurring in chorion-epithelioma in a woman aged 23. She had previously given birth to one stillborn child and to twins who died shortly after delivery. After antisyphilitic treatment she gave birth to an apparently healthy baby six weeks before she was admitted to hospital with vaginal bleeding. She was encephalitic, but no notice was taken of the nature of the curettings. She was subsequently readmitted with pyrexia, and what appeared to be placental tissue was removed; again no examination of the scrapings was made. Haemorrhage continued and hysterectomy was considered. The patient, however, developed cerebral symptoms and rapidly became comatose; respiratory difficulty supervened and death ensued. At the autopsy a large necrotic cavity was found in the right frontal lobe, a solid tumour half an inch in diameter was present in the occipital lobe, and there were five small scattered dark haemorrhagic growths. The uterus was enlarged and its cavity was clean. There was an intramural tumour about the size of a golf ball in its posterior wall, a pedunculated growth in the region of the right cornu, and a third small mass along the length of the right tube. No ovarian cystomata were present and no secondary growths in the vagina. In the lungs a few small secondary growths, half an inch in diameter, were found. All these growths showed the typical structure of chorion-epitheliomata. The author emphasizes the importance of a microscopical examination of curettings, and draws attention to the characteristic history in this case of recurrent haemorrhage associated with pregnancy. The report is illustrated with microphotographs.

#### 220. Ovarian Carcinoma with Uterine Myoma in the Aged.

ACCORDING to L. TIXIER and E. POLLOSSON (*Gynéc. et Obstét.*, 1925, xi, 1, p. 1), the formation of malignant ovarian tumours in elderly women who for many years have had uterine myomata is not uncommon and is associated with considerable diagnostic difficulty. Occasional attacks of abdominal pain are attributed by such patients to their myoma; and the same explanation is apt to be assumed—both by patient and surgeon—to hold good when one day a severe "attack" occurs, followed by loss of weight, deterioration of general health, pyrexia, ascites, and vesical or rectal symptoms. The myoma is found to have undergone no change in size or consistence, so that malignant transformation of the old tumour can probably be excluded. The absence of haemorrhage and offensive vaginal discharge as well as examination of the cervix serve to exclude cancer of the uterine body or neck. At the same time the fever suggests an inflammatory condition, a diagnosis which is apparently confirmed by the detection of soft, fixed, and tender swellings in the region of the adnexa. Malignant disease of the ovary is not suspected, or suspected too late, being discovered, at a laparotomy, usually in the form of an irregular tumour with vegetations and metastases. Such cases supply yet another confirmation of the view that all myomatous symptoms after the menopause should arouse grave suspicion. In these elderly subjects it is usually wiser, in operable cases, to deal with the ovarian tumour only and to avoid hysterectomy. Seven illustrative cases are recorded, with three recoveries.

## Pathology.

#### 221. The Intradermal Reaction in Typhoid Fever.

S. COSTA, L. BOYER, and E. GIRAUD (*C. R. Soc. de Biologie*, January 23rd, 1925, p. 93) have been investigating the response of patients suffering from typhoid fever to the intradermal injection of small quantities of a filtered typhoid culture. The *B. typhosus* was grown in broth for three weeks at 37° C., filtered through a Chamberland L3 candle, and heated to boiling point for twenty minutes. The injection was made in a dose of 0.1 to 0.3 c.cm. of the pure, or the diluted, filtrate on the anterior aspect of the forearm or the thigh. In the case of a negative reaction there was no more than a slight transient redness without oedema or pain, lasting not longer than twenty-four hours, and presumably due to the proteins

of the broth. On the other hand, in the case of a positive reaction there was a severe local response characterized by the formation of a large, red, oval, oedematous elevated patch extending over practically the whole of the forearm or over about half of the anterior aspect of the thigh, accompanied by a considerable amount of pain—sufficient in some cases to necessitate the protection of the skin from the pressure of the bedclothes. In addition to this local reaction there was a marked constitutional effect manifested by fever and sometimes by vomiting. When the diluted filtrate was employed the local reaction was generally less pronounced, and consisted in a small central elevated papule surrounded by a zone of redness of the size of a one- to two-shilling piece; the lesion was painful and it was noticed that this pain did not subside till after the erythema and oedema had disappeared. As regards the results obtained by the use of this method it was found that in fifteen cases of typhoid fever the reaction was negative, whereas in twelve cases in the convalescent or cured stage the reaction was strongly positive. In eleven patients suffering from diseases other than typhoid fever it was positive; it was likewise positive in a normal individual. The authors conclude from this that during the febrile stage of typhoid the intradermal reaction is negative, but that as soon as convalescence sets in and the patient becomes convalescent it changes to positive. Only two exceptions were noted—a positive reaction in a case of typhoid and a negative one in a homipleptic patient 72 years of age. Those results are different in many respects from those found in other diseases, and the authors realize that more confirmation must be obtained before they can be accepted.

#### 222.

#### Vitamins in Cow's Milk.

ETHEL M. LUCE (*Biochem. Journ.*, No. 6, 1924, p. 1279) finds that the diet of a cow is the principal factor in determining both the growth-promoting value and the antirachitic value of her milk. When the diet is deficient in fat-soluble vitamins, sunlight, of summer intensity in this country, has no appreciable effect in raising the growth-promoting value of the milk, though it appears to have some small influence over the antirachitic value. The converse of this has also been shown to occur, for when a cow was fed upon fresh green food in the absence of light, an increased "growth value" of the milk was observed, without corresponding improvement in the antirachitic value.

#### 223.

#### A Filterable Virus in Rabbits.

C. P. MILLER, C. H. ANDREWES, and H. F. SWIFT (*Journ. Exper. Med.*, December 1st, 1924, p. 773) report the discovery of a filterable virus infection of rabbits, communicable from one animal to another; the rabbits after such inoculation eventually become immune. The authors discovered this virus while studying rheumatic fever and using rabbits as experimental animals. In collaboration with Rivers and Tillett they found that the virus was identical with that described by these two authors as Virus III, which was discovered by Tillett when investigating experimental chicken-pox in rabbits; it was found eventually that it was not the cause of this disease. The discovery of this virus, the authors add, is of importance now that so much attention is being directed to filterable viruses in such diseases as encephalitis lethargica, since it will be necessary to immunize the rabbits to it before the investigation is commenced. The authors consider that such immunization is easily practicable, and that, after it, confusion in virus research is unlikely. They found also that the use of benzene did not appreciably increase susceptibility to the virus. They believe that the virus is probably present in apparently normal rabbits, but up to the present the ordinary course of the infection has not been brought to light.

#### 224.

#### Scurvy and the Ultra-violet Rays.

JANET H. CLARK (*Science*, January 9th, 1925, p. 45) calls attention to Lind's *Treatise on Scurvy*, written in 1757, in which it appeared to be indicated that the lack of sunlight, rather than the presence of moisture, might have been the cause of outbreaks of scurvy which occurred during the rainy season. She then reports three experiments in which groups of guinea-pigs were fed on different diets, all deficient in the antiscorbutic vitamin; these experiments showed that ultra-violet radiation was entirely ineffective in preventing or postponing scurvy. With diets in which other factors besides the antiscorbutic vitamin were lacking, ultra-violet light appeared indeed to hasten the loss of weight and subsequent death, and even to prevent recovery after the addition of vitamins to the diet. This, however, did not occur when a diet was employed in which the antiscorbutic vitamin alone was lacking.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 225. Syphilis of the Liver.

L. BLUM (*Journ. de Méd. et de Chir. Prat.*, December 10th, 1924, p. 837), discussing the frequency of syphilitic infection of the liver, remarks that while some authors consider that the great majority of those diseases of the liver which are not due to any obvious cause are due to syphilis, others think that the importance assigned to this disease has been exaggerated. Blum believes it is incontestable that the number of cases of syphilis of the liver tends to increase, but suggests that this may be due to greater accuracy of clinical and serological diagnosis. The liver may be attacked by syphilis in its secondary and tertiary stages. In the former jaundice appears early, at first simulating the catarrhal type, but persisting for an unusually long time, or assuming the haemolytic type with consequent anaemia. No clinical sign distinguishes this syphilitic hepatitis from those forms due to some other toxic agent. In the tertiary stage the liver may be large, painless, and irregularly bossed; there may be ascites and symptoms of atrophy or hypertrophic cirrhosis; but single or multiple gummata are very rare. Syphilis and alcoholism are frequently associated, and in many cases a history of a chancre or a positive Wassermann reaction shows that syphilis is a modifying agent in an apparently common type of hepatic cirrhosis. A large gumma or massive hypertrophy of the liver may simulate primary or secondary carcinoma; or, again, a gumma in process of breaking down may be mistaken for hepatic abscess, more especially since it is usually accompanied by fever and pain. Another form of syphilis of the liver is characterized by pain in the hepatic and splenic regions, associated with a very definite peritoneal "rub." Blum adds that the diagnosis of hepatic syphilis is often difficult: there is always the possibility that an obscure hepatic disease may be syphilitic in spite of the absence of clinical and serological signs; or, again, a syphilitic patient may suffer from some concurrent hepatic disease such as catarrhal jaundice. In all obscure cases, especially those in which surgical intervention is contemplated, every method of diagnosis of syphilis should be employed, including (if necessary) the test of treatment. Blum considers that this is the most valuable means of diagnosis in obscure cases, but he states that all hepatic cases do not tolerate treatment well, especially if large doses are employed. These patients are particularly sensitive to arsenical preparations, which should be given cautiously; and it is advisable to prescribe mercury, iodides, and bismuth by the mouth before having recourse to intravenous injections of any arsenical preparations.

### 226. Glycaemia in Parkinsonian Syndromes and Paralysis Agitans.

U. DE GIACOMO (*Rif. med.*, January 5th, 1925, p. 1) studied the blood sugar in eight cases of the Parkinsonian syndrome following epidemic encephalitis and in five cases of typical paralysis agitans, with the following results. In patients with the post-encephalitic Parkinsonian syndrome hyperglycaemia was constant. The phenomenon could be attributed either to anatomical lesions in the higher nerve centres, especially the cortex, or to a special hepatic change which several observers have found in this disease. On the other hand, in patients with typical paralysis agitans hyperglycaemia was slight and inconstant. De Giacomo thinks that in all probability the hyperglycaemia in these cases was not connected with the disease itself, but with extrinsic factors, especially scintillia and cerebral arterio-sclerosis.

### 227. Concurrent Malaria and Paratyphoid Fever.

J. L. VAN BODEGOM (*Nederl. Tijdschr. v. Geneesk.*, December 27th, 1924, p. 3251) remarks that malaria is often a dormant infection which needs some factor, severe fatigue, childbirth, or even a psychical trauma such as fright, to rouse it into activity. He records the case of a lad, aged 19, who was suddenly taken ill with a temperature of 103.1° and epistaxis. The third day he complained of pain in the left hypochondrium and upper part of the back. The tongue was coated and the spleen palpable. Examination of the blood showed numerous malarial parasites. A gram of quinine was given daily for nine consecutive days, and the temperature showed some tendency to fall, but after the tenth day the quinine did not appear to have any effect, and the temperature rose rapidly. On the eleventh day the association of a pulse rate of 84 with a temperature of 102.4° F. suggested

the possibility of typhoid fever, but the blood culture and serum test were negative. On the fifteenth day rose spots appeared on the abdomen, chest, and inner side of the right arm, and on the seventeenth day the serum test was positive for paratyphoid B (1 in 500) though the blood culture remained sterile.

### 228. Leucocytosis in Vaccinia.

K. KATO (*Amer. Journ. Dis. Child.*, December, 1924, p. 710) made a study of the nature of the leucocytosis following vaccination in 153 children under 18 months of age, and found that there was always a definite leucocytosis, which was both primary and secondary. The primary leucocytosis began on the third day after vaccination, and represented the general reaction of the organism to the invading virus. The total white count in primary leucocytosis was not so high as that of secondary leucocytosis, being about 13,300 per c.mm. Primary leucocytosis lasted about four days, reaching its maximum on the fifth day after vaccination. The secondary leucocytosis, the true leucocytosis of vaccination, began on the twelfth day and lasted seven to ten days, the average count being 19,140 per c.mm. The total white count was at its maximum on the fourteenth day after inoculation. The differential count, examined at various intervals after inoculation, showed no significant variations from the normal.

### 229. Infectious Diseases with Identical Course in Twins.

P. LERBOULLET, F. SAINT-GIRONS, and DENOYELLE (*Le Nourrisson*, November, 1924, p. 392) report the following cases in which infectious diseases in twins ran an almost identical course. The first pair of twins were sisters, aged 16 months, suffering from bronchopneumonia, which was treated by antipneumococcal serum. Both twins developed the serum rash at the same time. Both died within twenty-six hours of one another, and the autopsy showed identical pulmonary lesions in both cases. The second pair were sisters, aged 9, who contracted a severe attack of diphtheria within one day of each other. In both the serum eruption and paralysis of accommodation occurred at the same time, but one of the two developed strabismus as well. Both had paralysis of the palate, which occurred in one child forty-eight hours later than in the other, and both had difficulty in walking.

### 230. Epidemiology of Diabetes Mellitus.

H. EMERSON and LOUISE D. LARIMORE (*Arch. Intern. Med.*, November, 1924, p. 585), from a survey of numerous mortality statistics, conclude that the increase in the incidence and death rate of diabetes in the United States, and in New York especially, has been more rapid than that of any other disease recorded during the last fifty years. The highest death rate was among Jews, the lowest among the negro race in the United States. The relative rarity of diabetes amongst rural workers and those engaged in hard manual labour or trades would appear important; but lack of a satisfactory basis for calculating death rates according to occupation deprived the statistics of much of their value. The authors remark that, as regards geographical distribution in the United States, high death rates were found where there was a high proportion of the population in the later decades of life, after 45, where there were many Jews, and where individual wealth was prominent. Changes in food habits in the United States had probably contributed to the increase of diabetes, the higher carbohydrate element and greater abundance, or overalimentation, being believed to be a cause of overfatiguing the function of sugar tolerance. The question of the well established relationship between the increase of diabetes and the increased sugar consumption is discussed, but the latter is regarded as a sign of the tendency to excess of food of all kinds. The authors urge the importance of informing the public of the necessity of adjusting the food intake to exercise, and vice versa.

### 231. Orthostatic Albuminuria.

H. UYEDA (*Mittell. a. d. med. Fac. d. Kais. Univ. z. Tokyo*, November 4th, 1924, p. 247), who reviews the literature and records his observations on thirteen typical cases of orthostatic albuminuria in adult males, found that albuminuria following lordosis in the erect posture was greater than in recumbent lordosis. A very few casts, mostly hyaline and occasionally granular, red cells, and renal epithelium were to be seen in the urine after erect and recumbent lordosis. Chondroinuria was usually increased after both forms of lordosis, and there

was at the same time an increase in the acidity of the urine. As a rule it required about an hour for a recumbent kyphosis to cause the albuminuria to disappear. In exceptional cases a longer period, sometimes as much as eight hours, was needed. Although many individuals with orthostatic albuminuria showed a special sensitiveness for atropine, orthostatic albuminuria is not associated with any particular constitution. Of the signs indicating unstable equilibrium of the sympathetic nervous system the oculo-cardiac reflex was most often present in orthostatic albuminuria, respiratory arrhythmia was less frequent, and dermatographism was rarest of all. In some cases, in spite of the kyphotic position, albuminuria could rarely be produced by injection of adrenaline and pilocarpine. In such cases there was usually a lack of sensitiveness to these drugs. Suppression of albuminuria caused by erect or recumbent lordosis could usually be effected by injection of atropine, adrenaline, or pilocarpine. The majority of cases of orthostatic albuminuria react very distinctly to atropine. The suppression of erect or lordotic albuminuria by atropine shows that orthostatic albuminuria is not to be explained merely by renal congestion.

### 232. Complications in Diabetes.

M. ROSENBERG (*Klin. Woch.*, January 22nd, 1925, p. 159) draws attention to the remarkable fact that, whilst most complications of diabetes (especially septic complications) diminish the sugar tolerance and increase the risk of coma, certain complications cause the glycosuria to subside. In mild diabetes with increasing arterio-sclerosis in the heart and kidneys the glycosuria may disappear and only the hypoglycaemia may remain. Also in cirrhosis of the liver complicating diabetes the glycosuria may disappear; and the same disappearance of glycosuria has been often recorded in diabetes complicated by phthisis. Many instances of such diminution or disappearance of glycosuria in diabetes have been recorded and different explanations have been advanced. Rosenberg records four cases of severe diabetes in which remarkable increase of the carbohydrate tolerance and diminution of the acidosis occurred. In one case complete disappearance of the glycosuria and acidosis was observed on an almost normal diet, when complications developed. In three of the cases the complication was pulmonary tuberculosis; in one case bronchitis and empyema. Such a complete change in the metabolism has been attributed by some authors to marked diminution of the body tissue. Rosenberg considers that in his cases this view was not tenable, and that there must be some other cause for the pronounced increase in carbohydrate metabolism.

## Surgery.

### 233. Conversion of a Pelvic Sarcoma Into an Osteoma.

H. WACHTEL (*Journ. de Radiol. et d'Electrol.*, December, 1924, p. 543) describes the case of a girl of 18 who had suffered from pain in the right hip for two years. A tumour as large as a child's head developed and caused pain in walking; for some months progressive cachexia was present. A skiagram showed extensive decalcification and destruction of the right iliac crest, with some decalcification of all the pelvic bones. The deep abdominal glands were palpable and tender. In September, 1922, one of these glands and a small portion of the tumour were excised and the wound closed; both showed a sarcomatous condition with giant cells. The patient's weight was only 7 st. Above the left iliac fossa a chain of partly adherent glands, varying in size from that of a filbert to that of an apple, could be felt. Five daily applications of x rays, each of twenty-five minutes' duration, were made over the anterior surface of the tumour; 10 Holtzknicht units with a current of 1.5 milliamperes with a 2 mm. aluminium filter and skin-focus = 24 cm. The results were surprising; the circumference of the body at the tumour level was reduced from 35 to 32 inches, and the area of the projecting portion of the tumour was reduced by 2 inches. During the next five days similar doses were applied to the posterior wall of the pelvis. The patient gained 5½ lb. in seventy-two days. The treatment was continued at intervals of two months. The only effect on the skin was the production of slight erythema with subsequent pigmentation. In February, 1923, the glands on the left iliac crest were slightly smaller and painless, and skiagrams showed extensive recalcification of the pelvic bones. The patient continued to gain in weight; menstruation had been absent for some months prior to the commencement of treatment, but in June, 1924, it had become regular and the patient weighed 9½ st. As the patient made such rapid progress it had been decided to discontinue irradiation after the third series, which commenced on January 23rd, 1923. At the time of reporting the "reconstructed" bone was thickened and irregular, presenting the appearance of a series of exostoses, while the original osteo-

sarcoma appeared to have been converted into an osteoma. The patient was still under periodical observation on account of the well known fact that sarcomata, apparently cured by irradiation, may recur locally or by metastasis.

### 234. Perinephritic Abscess.

V. C. HUNT (*Journ. Amer. Med. Assoc.*, December 27th, 1924, p. 2070), from a review of the literature and consideration of 106 cases of perinephritic abscess in the Mayo Clinic, concludes that there is no instance in which primary infection of the perirenal tissues resulted in abscess formation independent of primary renal or extrarenal infection. Such abscesses may be of renal origin, resulting from pyonephrosis, lithiasis, tuberculosis, or traumatism; of extrarenal or metastatic origin; or may be produced by direct extension. He concludes that early drainage with primary or secondary nephrectomy gives the best results, simple primary drainage frequently reducing the risk of a later nephrectomy. An abscess secondary to lithiasis, and with little renal damage, generally responds to removal of the stone and simple drainage. Metastatic abscesses or those secondary to single cortical abscesses seldom require more than simple drainage. N. F. OCKERBLAD (*ibid.*, p. 2074) reports ten cases of perinephritic abscess in which a careful urological examination was made. Diagnosis of the condition rests mainly upon pain, loin tenderness or swelling, remittent fever, and a high leucocyte count. It is pointed out that in all the cases the urological examination of each kidney gave findings which determined the line of treatment. Seven of the abscesses were right-sided and three left-sided; five patients were treated by nephrectomy and drainage, and five by drainage alone. Early operation based upon a complete urological examination is advocated.

### 235. Ostitis after Dental Extractions.

M. MELCHIOR (*Ugeskrift for Læger*, January 8th, 1925, p. 23) gives an account of fourteen patients who, long after a dental extraction, suffered from a chronic destructive ostitis, with the formation of a cavity, as small as a pea or as large as a walnut, in the jaw. Such cases, he thinks, cannot be very rare, as these fourteen patients were seen within a period of three years. Nearly all of them had been previously treated without the correct diagnosis being made, and it would seem that ignorance of the existence of this condition is the chief reason for its being neglected. In six cases there was an interval of two to fifteen years between the dental extraction and the diagnosis of the ostitis. Chronic periodontitis being very common, the author asks why the extraction of the offending tooth so seldom gives rise to the chronic ostitis he describes, and he suggests that the development of this condition may depend on several factors, such as advanced inflammatory disease at the time of the extraction, the existence of a granuloma which is not wholly removed when a tooth is extracted, and severe injury to the bony structures at the time of the extraction. The bony cavity always communicates with the mouth by one or more fistulae, and in many cases the symptoms may be absent or only slight, such as a little local tenderness. But there may be severe pain and tenderness, as well as trigeminal neuralgia. In addition to the local discomfort and pain, there is always the possibility of a more generalized infection, and for this reason, and because there is no prospect of spontaneous recovery, radical operative treatment is required.

### 236. The Surgical Treatment of Angina Pectoris.

D. DANIELOPOLU (*Bull. et Mém. Soc. Méd. des Hôpitaux de Bucarest*, October, 1924, p. 193) repeats his assertion that the ideal surgical treatment of angina pectoris is the removal of the largest number of cardio-aortic sensory fibres with the least possible injury to the efferent fibres, the division of the latter being likely to produce serious results. He condemns Jonnesco's operation (cervico-thoracic sympathetomy), which fulfils the first condition but ignores the second. The latter is the more important condition, since when the division of the cardio-aortic sensory fibres is incomplete the operation may not relieve the patient, but when the cardiac motor fibres are divided there is great danger of death from acute myocardial failure or from acute pulmonary oedema. At a congress in Vienna in March, 1924, Brünning alone recommended cervico-thoracic sympathetomy, having had one successful case; but in all cases so far recorded the fatalities outnumber the successes. Daniélopou adds that surgical intervention in angina pectoris is made more difficult by its anatomical variations of the cervical sympathetic and its branches, and that some authors make a mistake in not recognizing the depressor nerve as a cardio-aortic sensory nerve. He believes that there are two groups of sensory fibres—ascending and lateral. The former pass upwards from the cervical spinal nerves, cervical sympathetic, and vagus; the latter run in the rami communicantes which connect the first thoracic and inferior cervical ganglia with

the eighth cervical and first four dorsal spinal nerves. The author considers it probable that the cervical sympathetic contains the greater number of the cardio-aortic sensory fibres, and states that there is little danger in excising the superior ganglion, the middle ganglion (when present), and the sympathetic trunk to a point just above the inferior cervical ganglion. The cardio motor fibres run chiefly through the inferior cervical and first thoracic ganglia; any motor fibres contained in the branches of the sympathetic above this point may, he adds, be divided without risk, provided that the inferior cervical and first thoracic ganglia are not damaged. Danićopolu remarks that it cannot be repeated too often that it is never necessary to touch the inferior cervical and first thoracic ganglia, as the extirpation of the cervical sympathetic must terminate at a point above the former. As the left side of the heart is the chief site of pain during an anginal attack, it is advisable to operate first on the left cervical sympathetic. It is probable that in the majority of cases an operation on the left side only will suffice.

### 237. Blind-end Circular Suture of Intestine.

W. F. REXNORTH, junior (*Bull. Johns Hopkins Hosp.*, January, 1925, p. 81), reports a case of sigmoid carcinoma treated by Halsted's method of blind-end circular suture of the intestine. The bowel was clamped 2½ inches above and below the growth, and four purse-string sutures were inserted, between each pair of which the bowel was divided with the cautery. Two mattress sutures were placed on both sides of and immediately in the mesentery, one in the anterior mesenteric border and one on each side of the lateral borders of the intestine. Others were placed about one-tenth of an inch apart and reinforced by interrupted sutures, making about sixteen sutures in all. A cork-tipped knife was inserted per rectum to the point of anastomosis, and, after removal of the tip, was passed through its centre, cutting the purse-string suture. After its withdrawal a bougie was passed to dilate the opening further. It is stated that the advantages of the operation are that there is no soiling, and post-operative adhesions are avoided. It is claimed that it can be more rapidly executed than open anastomosis, necessitates less handling of the bowel, provides ideal peritoneal apposition, and, by permitting the insertion of a rectal tube beyond the line of anastomosis, obviates the necessity for a colostomy, so preventing post-operative discomfort and distension. The author advocates its performance in selected cases, especially those in which the growth is localized and the performance of a lateral anastomosis would necessitate undue stretching and subsequent tension.

### 238. Afebrile Erysipelas.

A. TATA (*Studium*, January 20th, 1925, p. 22) reviews the literature, and records the case of a boy, aged 10, who presented all the characteristic features of facial erysipelas, but without any rise of temperature or any cerebral symptoms due to the action of streptococcal toxins on the brain, such as delirium, loss of consciousness, or headache. Complete recovery followed in the course of ten days after treatment by local applications of guaiacol oil and injections of colloidal preparations. Tata quotes other examples of afebrile erysipelas from the textbooks of Mohr and Stachelln, Fecr, Rummo, Leube, and Zagari, and regards such cases as an expression of an infection attenuated by the systemic defences of the individual.

### 239. Peptic Ulcer after Gastro-enterostomy.

D. MARIO and F. RICCIO (*Arch. Ital. di Chir.*, December, 1924, p. 821), in view of the various opinions as to the cause of this ulcer, have carried out a series of experiments on dogs to elucidate the problem. They first discuss some of the explanations hitherto advanced, such as the traumatic, peptic, vascular, infective, and diathetic theories. They then describe their experiments on twenty-six dogs, divided into six groups according to the nature of the operation—gastro-enterostomy, duodenal exclusion, pyloric resection, with various types of anastomosis. With one exception none of these operations was followed by ulcer, and the authors conclude that if useless traumatism, sepsis, and the use of non-absorbable sutures in the mucous and muscular layers are avoided no ulcer will follow. One source of ulcer may be interference with the nerve ganglia in ampie resections, coupled with the toxic power of stagnant duodenal contents and a concentration of digestive juices. Silk sutures, they add, should be avoided except for the sero-muscular coats, and as far as possible clamps should not be used. Sutures should not perforate the mucosa. It is important to secure that the new stoma should function properly. Removal of the pyloric part does not seem to increase the peptic power of the gastric juice, and Mario and Riccio agree that the healthy jejunal mucosa is absolutely indifferent to the gastric secretion.

## Therapeutics.

### 240. An Internal Urinary Antiseptic.

V. LEONARD (*Journ. of Urology*, December, 1924, p. 585) reports the discovery of an internal urinary antiseptic which is non-toxic and a most powerful germicide. He found that by increasing the molecular weight of the alkyl chain in alkyl resorcinols a pronounced increase in bactericidal quality was obtained with a coincident diminution in toxicity to laboratory animals. Thus, whereas the phenol coefficient of resorcinol was 0.3, in the case of isobutyl resorcinol it was 15.2, and in hexyl resorcinol 45. The bulk of each oral dose given is excreted as an inert compound; therefore a dose of 0.3 to 0.6 gram three times a day is necessary to ensure a practically continuous flow of bactericidal urine. The substance appears to be inert in its passage through renal epithelium, and is therefore of little, if any, value in the case of infections which have invaded the parenchyma of the kidney. Urinary infections due to Gram-positive cocci were found usually to clear up quickly and permanently after oral administration of hexyl resorcinol, and *B. coli* infections were similarly cured if the bacterial count in the urine was low. But with the usual high count of *B. coli* infections the mass action of the free hexyl resorcinol excreted in the urine was insufficient to complete the disinfection until the count was reduced by local treatment. Persistent treatment for from thirty to sixty days was generally necessary in these cases. Prolonged administration appeared to result in no injury to the kidney or irritation of the urinary tract. The bactericidal action was unaffected by changes in the reaction of the urine. Leonard recommends that hexyl resorcinol should be administered in capsules or pills coated with salol to prevent or retard their disintegration in the stomach. He finds that it forms a very soluble non-irritating salt in the alkaline intestinal fluids.

### 241. Treatment of Anginal Attacks.

L. STEIN (*Med. Klin.*, January 18th, 1925, p. 95) specially recommends nitroglycerin in the treatment of angina pectoris. Though it was strongly recommended by Nothnagel, and though its action is everywhere recognized, it is relatively seldom used in Austria. Nitroglycerin can be taken for long periods without bad effects; the author mentions a patient who was ordered daily two tablets, each containing 1/2 mg. of the drug, for a time, but instead of following these instructions he took four or five tablets daily continuously for twenty years, until his death from pneumonia at the age of 85. The author also advises morphine (which many fear to give). It relieves the pain and the spasm of the coronary vessels, and often saves life. Dry warm local applications are of service. By permanently diminishing the blood pressure the frequency and intensity of the attacks are reduced. Stein adds that though different views are held as to the mode of origin of anginal attacks, it is certain that they occur only when the blood pressure is high. The indication for checking the attacks of angina (in addition to other treatment) is the diminution of the blood pressure by suitable diet and by the administration of theobromin and diuretin for many years.

### 242. Autoserums in Chorea.

J. DINER (*Med. Journ. and Record*, January 21st, 1925, p. 91) reports fifty-nine cases of chorea minor treated successfully by intraspinal injections of the serum of the patient. Only one had a recurrence of choreiform movements two and a half years later, and these subsided after a week in hospital. Although the suspicion of a focal infection cannot always be substantiated many patients give a history of previous infection, and the author claims that the autoserum treatment has been so successful as to warrant further investigation. He believes that the passage of substances from the sub-arachnoid spaces to the blood takes place more easily than in the opposite direction, especially when there is an increased intraspinal pressure. Assuming chorea to be an infection in the cord, he thinks that the antigen reaching the circulation stimulates the production of antibodies which cannot get back into the spinal fluid owing to the lower pressure in the circulation and the obstacle of the choroid plexus. The introduction of the patient's serum rich in antibodies direct into the spinal space overcomes the infection. Diner gives notes of a case of a boy, aged 16, with the mentality of a boy aged 8, who had had several attacks of chorea variously treated without relief, in whom autoserum treatment caused cessation of the choreic movements within six days. For some time he was given anterior lobe pituitary gland extract, and two and a half years later he had improved mentally, and physically "beyond recognition" and was giving satisfaction as a clerk in an office.

## 243. Treatment of Typhoid Fever.

J. CHALIER and A. TOUR (*Lyon méd.*, December 21st, 1924, p. 781) have treated forty-four cases of typhoid fever by intravenous injections of hexamethylene tetramine associated with baths at a temperature of 82.4° F. The patients received daily doses of 10 c.cm. of a 20 per cent. solution, which was equivalent to 2 grams of the drug, and the treatment was continued until the temperature became normal, which required from two or three to four or five days. When the injections were carried out correctly there was no local reaction or pain at the site of injection, and the veins remained indefinitely permeable. The injections were well borne as a rule. No pruritus, eruption, circulatory disturbance, vomiting, or dysuria were observed. Shock was exceptional; it was noted in only five or six cases, and with one exception was slight, consisting in shivering and some rise of temperature. Although hexamine given by mouth gives rise to haematuria in from 7 to 12 per cent. of all cases of typhoid fever owing to the occurrence of vesical congestion, it was not found in any of the authors' cases in which the drug was given intravenously. With few exceptions the injections were followed by a diminution of delirium, stupor, fever, and diarrhoea, an increase of diuresis, and a general improvement. In no case did intestinal haemorrhage occur. Four patients died—a mortality of 9 per cent.—but one of the fatal cases was associated with a polycystic kidney, and the others were examples of typhoid fever following consumption of oysters; the gravity of these cases is well known.

## 244. Treatment of Tuberculosis by Ethyl Morrhuate.

A. GRIGAUT and A. TARDIEU (*Bull. Soc. de Thér.*, December 10th, 1924, p. 324) review the literature, especially the papers by Leonard Rogers (*BRITISH MEDICAL JOURNAL*, February 8th, 1920, and December 29th, 1923) on the treatment of leprosy and tuberculosis by sodium morrhuate, and remark that the drug has serious drawbacks which prevent its being widely used. In the first place it is an unstable product and can only be injected in a freshly prepared solution. Secondly, it often gives rise to a febrile reaction and swelling and redness at the site of injection, and is particularly liable to cause violent reactions in tuberculous foci. Thirdly, it is only soluble in water and quite insoluble in oil, so that it can only be used in subcutaneous or intravenous injection, while the tracheal route, which is the ideal method for treatment of pulmonary lesions, is impossible. To remedy these defects the authors have prepared the ethylic ether of morrhuate acid, or ethyl morrhuate, which is a stable body, insoluble in water, but soluble in oil, and only very slightly toxic, as shown by experiments on dogs. It has a pronounced cardiotonic action and is therefore of special value in phthisical patients, who frequently show tachycardia and signs of cardiac failure. The authors employ 5 to 10 per cent. solutions of ethyl morrhuate in olive oil for tracheal injections in pulmonary tuberculosis, but their observations have been too recent to justify any opinion as to the efficiency of the treatment. In subcutaneous injection ethyl morrhuate does not give rise to any local or general reaction in doses of under 1 c.cm., but when this dose is reached a slightly painful induration occurs at the site of injection at the end of twelve to twenty-four hours, and is only slowly absorbed.

## Dermatology.

## 245. Scrofuloderma Gummosum.

H. S. MICHELSON (*Arch. Derm. and Syph.*, November, 1924, p. 565), who records three illustrative cases, gives the name of "scrofuloderma gummosum" or "tuberculosis colligativa" to a distinct type of cutaneous tuberculosis, which does not necessarily arise from tuberculous glands or bones but may begin in the cutis or subcutaneous tissues. The condition is most frequent in children, in whom the skin overlying tuberculous glands, bones, or joints is likely to be affected. In adults the face, neck, and areas over bony projections and epiphyseal regions are most often invaded. The onset is usually insidious with an indolent infiltration of the skin or subcutaneous tissue. There may be a solitary node, a group of several nodes, or a conglomerate mass which may remain unchanged for weeks, causing no pain. A slight inflammatory zone then develops about these areas, and considerable pain arises. The overlying skin becomes discoloured and the central portion softens. The onset gives issue to only a small amount of fluid, but on incision perforation takes place several small openings may form simultaneously with slow elimination of their contents. Superficial tracks may develop along the lines of the lymphatics forming the so-called tubular scrofuloderma. After perforation fistulae, abscesses, and ulcers result, and may remain unaltered for a long time. The edges of the ulcers are thin, frayed out, and undermined, sometimes

sorapigulous. The base is granular, and the discharge consists of a tenacious pus. The condition is most likely to be confused with a syphilitic gumma. In the nodular stage clinical differentiation is sometimes almost impossible, but after ulceration the distinction may be somewhat easier. When the lesion is over a projecting bone the conditions are almost identical and the diagnosis must depend on the serological and bacteriological findings. Age is of some help in that tuberculosis is commoner in childhood and adolescence, especially in the cervical region. The evolution is as a rule more rapid in tuberculosis. Scars when present are a help: the syphilitic scar is thin, glistening, and almost transparent, with a pigmented areola, while in tuberculosis there is a thick heavy keloid-like scar which may cause distortion of the part. Sporotrichosis is differentiated by the arrangement of the lesions along the lymphatics, the acute onset, crateriform, superficial elevated lesions, and the results of cultures. The prognosis depends on the strength of the individual. There is usually a marked tendency to spontaneous healing, but local recurrences are common. There is no specific therapy, but x rays, heliotherapy, and tuberculin have been recommended. General treatment is the same as in any form of tuberculosis.

## 246. Treatment of Hypertrichosis.

T. KATZ (*Dermat. Woch.*, November 15th, 1924, p. 1492) states that epilation for hypertrichosis has always been disappointing hitherto. The use of x rays has not fulfilled previous expectations, the risk of damage to the skin even with filtered rays far outweighing the prospects of success. The most practical method hitherto employed, rendering the hairs invisible by bleaching them, is only suitable when the individual hairs are fine, since thick and bristly hairs are as unsightly when bleached as when they are dark. Electrolysis of each individual hair demands much time and care from the practitioner and causes considerable pain to the patient, with little prospect of success. Katz has recently obtained excellent results in the treatment of hypertrichosis by diathermy. The hair papilla is destroyed by heat with a relatively weak current in one to two seconds. The pain caused by this method is comparatively slight, being much less than that produced by electrolysis. He adds that after treatment by diathermy the hairs are easily removed by forceps. Necrosis and scars are not more frequent than after electrolysis, and are best prevented by using a current which does not cause more than a slight feeling of heat.

## 247. Urticaria Pigmentosa.

M. G. HANNAY (*Brit. Journ. Derm. and Syph.*, January, 1925, p. 1) reports an experience of over seventy cases of urticaria pigmentosa occurring in adults over 15 years of age. He sees no reason for separating cases of chronic pigmentary urticaria from urticaria pigmentosa, either on grounds of age incidence, clinical characteristics, or absence of mast cells. Although a certain type of infantile urticaria pigmentosa may be rare in adults, the clinical features usually occurring in adults are often seen in children and do not constitute a distinct adult type. All degrees of mast-cell infiltration occur in both types, and cases clinically resembling urticaria pigmentosa occur in which mast cells are absent. Mast cells may be more constantly present in infantile cases, but their absence does not appear to be dependent upon the age either of the patient, or of the onset, or of the lesion. No definite clinical characteristic, such as the degree of urticarial reaction, or the size, colour, or type of the lesion, distinguishes mast-cell-free cases from others.

## 248. Tuberculosis of the Face simulating Oriental Boli.

A. LOUSTE, L. LOUET, and J. DARQUIER (*Bull. Soc. Française de Derm. et de Syph.*, December, 1924) report the case of an Armenian boy, aged 15, in whom a small nodule, the size of a lentil, appeared on the left cheek shortly after his arrival in France in May, 1924. It was cauterized with silver nitrate, but continued to grow until, on admission to hospital in November, it was as large as a 5-franc piece, and projected 1 cm. above the surrounding tissues. The peripheral portion was slightly nodular and of a reddish-violet colour; the centre was ulcerated and covered with yellowish-brown scaly crusts; the ulcer was deep red, without granulations, and did not suppurate or bleed. The tumour was somewhat soft and rested on an indurated, though slightly infiltrated, base. At the periphery the inflamed lymphatics could be rolled under the finger, and at the angle of the jaw an inflamed lymph node as large as a hazel nut could be felt. All the internal organs were normal. The clinical appearances and the histological findings suggested the diagnosis of Oriental Boli. The analysis of the blood and serum from the ulcer gave negative results. A section showed many giant cells in which the Ziehl-Neelsen stain showed numerous tubercle bacilli; these were also found in certain areas in which caseation was proceeding. It was thus recognized as

being a typical tuberculous lesion undergoing degeneration without fibrosis. Jeansolino, discussing the case, observed that, whilst it was possible to mistake cutaneous tuberculosis for Oriental boil, the converse error occurred more frequently. He related the case of a medical officer from a region of the Sahara in which Oriental boil was endemic. The whole of the left cheek and ear were covered by a lupoid dermatitis which disappeared spontaneously three weeks after the patient's return to France. A similar case was that of a priest who had been to Palestine; he had numerous sluggishly-ulcerating areas in the presternal region which were thought to be tuberculous. They healed spontaneously. It is added that the presence of giant cells does not settle the question; Leishman-Donovan parasites and tubercle bacilli must be sought in the tissues, since the pus may be sterile.

## Obstetrics and Gynaecology.

### 249. Operative Treatment of Contracted Pelvis.

G. FOSSATI (*Ann. di Ostet. e Ginecol.*, December 31st, 1924, p. 611) discusses the scope and results of operations designed to secure permanent enlargement of contracted—especially flat—pelves. These operations are: (1) the Rotter-Mauglagalli resection of the sacro-vertebral angle; (2) Costa's partial superior symphysiotomy, in which a wedge-shaped portion of the postero-superior part of the pubes is removed, extending between the two pubic spines (1920); (3) a combination of these two operations. Recently one or other of these methods has been combined with Caesarean section. The immediate maternal prognosis has been uniformly good; with regard to the foetal prognosis, Costa reports one foetal death only in twenty-three cases, but in the present paper Fossati records seven cases of Costa's operation with only four survivals of the infant. As proof of the benefit conferred by the permanent lengthening of the pelvic conjugate Schmid has recorded six instances (in two patients) of live and, as a rule, spontaneous birth in pregnancies occurring subsequently to excision of the sacro-vertebral angle; Fossati has seen two similar results after the same operation; and Fraenkel witnessed an equally gratifying sequel after resecting the promontory in a flat pelvis with a true conjugate of 6.5 cm. Three cases have already been reported, and Fossati cites another, of spontaneous delivery of a live child at term in pregnancies following Costa's operation. Turning to technique, Fossati recommends that in resection of the sacral promontory a collar of periosteum should be removed around the excision of bone, to avoid production of spurious bony upgrowths, as reported by Schmid; rather than excise two bulky portions from this region it is better to combine the operation with Costa's procedure. Symphysiotomy is recommended in cases of true conjugates down to 8 cm.; the combined operation for conjugates of 8 to 7 cm. In spite of Fraenkel's successful case, already quoted, the advisability of extending the operations to pelvis having a conjugate of less than 7 cm. is questionable. Fossati points out that there is much to be said for combining Costa's operation with Caesarean section in cases seen at a stage when the latter is possible. If labour is terminated naturally after symphysiotomy the foetal life is to some extent endangered by uterine inertia and the effect of narcotics. He is convinced that at the operation of Caesarean section for dystocia due to pelvic contraction only it is correct to carry out one or other of the procedures which permanently enlarge the pelvis; if this is done there is a good prospect of spontaneous termination of subsequent pregnancies and second Caesarean operations will become rare.

### 250. Caesarean Operation in Two Stages.

L. CLEIZ (*Bull. Soc. d'Ostet. et de Gynecol. de Paris*, 1924, 9, p. 725) records four cases of Caesarean section followed by temporary "exteriorization" of the uterus, which was restored to the pelvis at a subsequent operation. This two-stage operation was first performed by Portes (*Epitome*, December 6th, 1924, para. 454). The first patient, a primipara aged 42, suffered from mitral disease, with failing compensation towards term. Twenty-one hours after the beginning of labour, and thirty-seven hours after rupture of the membranes, the head was not engaged, the liquor amnii was infected, and the maternal condition was grave. A living hydrocephalic infant weighing 3,700 grams was extracted. The second operation was performed thirty-three days later; drainage was not required. The second patient, a primipara aged 29, had a contracted pelvis; the first operation was performed forty-one hours after the beginning of labour, and the second twenty-eight days later. The third patient, whose uterus was myomatous, had been in labour sixty-eight hours; the uterine sutures gave way and a haematoma larger than the uterus formed in the broad ligament, but the patient

made a good recovery, hysterectomy being performed on the thirty-fifth day. The fourth patient came to operation with a temperature of 101.8°; general peritonitis ensued, and she died after hysterectomy on the fifth day, but the infant was saved. P. GUTHRIE (*ibid.*, p. 725) describes a successful two-stage operation in a case of impacted shoulder presentation. At the second operation on the forty-fifth day the uterus had disappeared beneath the integument and only the adnexa were still external to the skin. Six weeks later the uterus was of normal size and mobility.

### 251. Spontaneous Delivery of Hydrocephalus.

G. VAN DEN BERG (*Nederl. Tijdschr. v. Geneesk.*, December 20th, 1924, p. 3137) records the case of a primipara, aged 23, who had been pregnant twenty-eight weeks and in labour fourteen hours, in whom spontaneous delivery of a hydrocephalic child took place by head presentation. When the umbilical cord, which was coiled round the neck, was divided the rest of the child was easily born. The head was nearly twice the normal size, and the face was very asymmetrical. There were a spina bifida with much kyphosis and bilateral club-foot. The child gave no sign of life, although it did not show any cyanosis. Artificial respiration in a warm bath had no effect, which was probably due to the fact that the cranial cavity merely contained fluid, without any active respiratory centre.

### Chronic Cervicitis.

B. Z. CASHMAN (*Amer. Journ. of Obstet. and Gynecol.*, November, 1924, p. 628) doubts whether the problem of cancer of the cervix will ever be attacked with any degree of success until the precancerous condition of chronic cervicitis is extensively treated. He insists that chronic cervicitis can only be effectively dealt with by eradication or destruction of the deep glands of the cervix, and recommends cauterization of the cervical canal followed by careful after-treatment so that stenosis may be prevented. Cashman believes that cauterization may be conveniently performed during such an operation as appendectomy under general anaesthesia if any cervical lesions are present. After dilatation of the cervical canal to its full extent the whole of the cervical canal to a depth of one-eighth of an inch should be cauterized with the electro-cautery knife. At the external os six or eight radial incisions are made a quarter of an inch in depth and prolonged well on to the vaginal portion of the cervix. The treatment is concluded by a second thorough and complete dilatation of the cervix being made. Cashman remarks that this procedure constitutes a major operation and should not be considered as out-patient treatment.

### 253. Pregnancy and Heart Disease.

K. BJERRING (*Egeskrift for Læger*, January 29th, 1925, p. 95) finds, from a study of the literature on this subject that the view generally accepted during the latter part of the last century, that pregnancy exerts a most sinister influence on heart disease, is no longer held. It has given place to the conviction that the seriousness of the complication of heart disease has been much overrated. The author's own material consists of 9,800 women confined at a maternity hospital in Denmark. Among them there were 87 who suffered from heart disease, and as some of them were confined more than once there was a total of 107 confinements complicated by heart disease. After comparing his own statistics with those of others, the author concludes that from 1 to 2 per cent. of all confinements are complicated by heart disease. In his own material there were 48 cases of mitral regurgitation, and 21 of mitral regurgitation with mitral stenosis; there was not a single case of aortic regurgitation. The ratio of primiparae to multiparae was as 38 to 49, and the ages ranged from 17 to 44 years. In 60 per cent. there was a history of rheumatic fever, and in 25 per cent. there was no history of any infection which might have caused the heart disease; in the remainder there was a history of such diseases as diphtheria and scarletina which might have been responsible for the heart disease. Of the 107 pregnancies, as many as 53 were unassociated with any cardiac symptoms. In 23 cases the slight cardiac symptoms existing before pregnancy did not become worse while it lasted. In some other cases there was a slight aggravation of the symptoms during pregnancy, and there were only 11 cases in which severe and alarming symptoms complicated pregnancy; among these there were 6 cases terminating fatally soon after confinement. But the confinement could not be held responsible for all these deaths, and the author concludes that the risk of confinement killing a patient because she suffers from heart disease is less than 1 per cent. The risk, he finds, is greatest for elderly multiparae, and he is very sceptical as to the necessity for terminating pregnancy in most cases of even serious heart disease, although he admits that on very rare occasions the artificial interruption of pregnancy may be justifiable.

## Pathology.

### 254. Primary Thrombo-phlebitic Splenomegaly.

C. FRUGONI (*Arch. di Patolog. e Clin. Med.*, December, 1924, p. 574) describes five cases of thrombo-phlebitic splenomegaly. He points out that this disease is of a primary nature and must be distinguished from cases in which the thrombo-phlebitis is secondary to morbid processes in the vicinity of the spleen. Of the five cases three occurred in children and two in adult males. The course of the disease was extremely variable; one child, for instance, died in two years from the start, another died after the disease had lasted for thirty-seven years, and another was still alive after twelve years. The symptoms, too, varied to a certain extent, but the general picture was a splenomegaly accompanied by anaemia of the secondary type with leucopenia, followed later by repeated haematemesis and melæna, fever, and ascites. The enlargement of the spleen was very marked, but it varied in degree from time to time. The anaemia was not absolutely constant; it was particularly noticeable after haematemeses, when the red cells fell to between one and three million per cubic millimetre, with a colour index of about 0.5; the white cells were generally between one and three thousand per cubic millimetre, and this leucopenia was not infrequently accompanied by a relative lymphocytosis. One of the most surprising symptoms was the haematemesis, which increased in degree as the disease progressed. After each haematemesis the spleen diminished considerably in size, while a few days later an irregular fever set in accompanied by ascites, the fluid of which had the properties of a transudate. This sudden decrease in the size of the spleen following each haematemesis, with the subsequent fever and ascites, formed a very striking syndrome. Pathologically the essential lesion was a thrombo-phlebitis of the splenic vein and of the other branches of the left part of the portal system. Consequent on this there was dilatation of the smaller anastomotic vessels between the spleen and the stomach, the rupture of which gave rise to the haematemeses. The spleen itself was not only enlarged but showed an increase in the fibrous reticulum. As regards the etiology of the disease there does not appear to be any definite knowledge. The author discusses the differential diagnosis from cirrhosis of the liver and from Banti's disease; he concludes that this primary thrombo-phlebitic splenomegaly is probably more common than is generally supposed.

### 255. Histology of Duodenal Ulcer.

W. C. MACCARTY (*Journ. Amer. Med. Assoc.*, December 13th, 1924, p. 1894) discusses the pathology of duodenal and gastric ulcers, basing his conclusions on the examination of 522 specimens. Both gastric and duodenal ulcers, he states, are not infrequently multiple. The gastric ulcer tends to be larger than the duodenal ulcer, and to have a deeper crater; duodenal ulcers show less scarring and there is no hypertrophied mucosa overhanging the crater, as occurs in gastric ulcer. The duodenal lesion was usually found on the anterior wall of the duodenum, whereas gastric ulceration occurred most commonly on the posterior wall of the lesser curvature. The histological changes in duodenal ulcer were never suggestive of a pre-neoplastic condition, and the author encountered no pre-neoplastic condition in 425 specimens of this condition. In gastric ulcer, however, there were usually cytological changes suggesting early malignancy, and the author considers his observations to be in accordance with the clinical fact that gastric ulcer is frequently associated with malignant disease. There is, he states, a definite biological difference in their reaction to destructive agents of these two similar and closely related tissues which are so nearly adjacent. The author notes that in inflammatory conditions of the duodenum it may be difficult at an operation to tell if an ulcer is present or not. He considers that local congestion and stippling of the serosa is probably an indication of the presence of small round or elongated ulcers.

### 256. How Salt Preserves.

THE inhibiting effect of sodium chloride on bacterial growth has frequently been ascribed to its ability to dehydrate protein. Not content with this explanation, G. E. ROCKWELL and E. G. EBERTZ (*Journ. Infec. Dis.*, December, 1924, p. 573) have performed a number of experiments to determine the actual factors involved. Comparing the effect of sodium chloride and magnesium sulphate on the growth of *Staphylococcus aureus*, they found that the former salt had a more powerful inhibitory action than the latter, in spite of the fact that magnesium sulphate has a greater ability to dehydrate protein. Using the same organism, they then tested the effect of sodium chloride, sodium bromide, sodium

sulphate, sodium eltrate, magnesium chloride, magnesium sulphate, and magnesium eltrate, and found that the two eltrate salts had the greatest inhibitory effect on growth, followed by the chlorides, the bromides, and the sulphates—that is to say, the chlorine ion had a definitely noxious action on bacteria. Their next experiment was to compare the growth of *S. aureus* in broth containing various concentrations of sodium chloride, through one series of which oxygen had been bubbled and carbon dioxide through the other. The result was very striking. In the broth through which carbon dioxide had been passed the limiting concentration of sodium chloride was 2 per cent.; in the broth through which oxygen had been passed the limiting concentration was 16 per cent. Now it is known that sodium chloride is a poor solvent for oxygen, and the authors therefore infer that it interferes with bacterial growth partly through its ability to exclude oxygen and partly through its sensitizing capacity with regard to carbon dioxide. Finally, using *B. proteus*, it was found that 3 per cent. salt was the highest concentration which permitted the organism to liquefy blood serum, though its growth was not prevented till a concentration of 11 per cent. was attained. They think, therefore, that it is clear that sodium chloride interferes with the action of proteolytic enzymes. In conclusion, they say that there are at least four factors involved in the preserving action of salt on proteins—namely, its dehydrating effect, the direct effect of the chlorine ion, its removal of oxygen and sensitization to carbon dioxide, and its interference with the action of proteolytic enzymes.

### 257. Influence of the Parental Diet in Rats on their Offspring.

V. KORENCHESKY and MARJORIE CARR (*Biochem. Journ.*, No. 6, 1924, p. 1308) have previously shown that feeding a male rat on a diet deficient in the fat-soluble factor had no influence whatever upon the number, weight, and chemical composition of its offspring. Continuing their investigations upon the litter at the day of weaning and later, the authors have come to the following further conclusions. (1) If the diet of the adult males had been deficient in the fat-soluble factor a higher percentage of matings was unproductive. (2) The litter also seemed to be weaker. (3) No difference was noted in the weight of the young nor in the calcium composition of their skeletons. In their earlier experiments the authors found that if the diet of the mothers before conception and during pregnancy contained an excess of fat-soluble factor and calcium the litters were larger in number than those borne by mothers on the usual or fat-soluble deficient diets. They also found that a deficiency of fat-soluble factor in the mother's diet would be remedied by a sacrifice of her own tissues to her offspring, the chemical composition of the litter thus remaining normal. In the present series of investigations the effect of a diet deficient in fat-soluble factor on the mothers during lactation and the young after weaning in the first group were noted, and the following observations were made. When the mother's normal diet during pregnancy was enriched with an excess of the fat-soluble factor there was a marked decrease in the disorders of the general nutrition and in the rachitic changes in the skeleton produced in the young by a diet deficient in fat-soluble factor, even when the mother was also kept on the same insufficient diet during lactation. This effect was not produced by giving an excess of calcium during pregnancy, provided that the mother's "normal" diet already contained an adequate amount of calcium.

### 258. A New Test for Pernicious Anaemia.

O. TÖGEL and P. CERANKE (*Wien. Arch. f. inn. Med.*, December 10th, 1924, p. 301) record their results of the examination of the blood in pernicious anaemia and other diseases with respect to its power of decomposing hydrogen peroxide. The amount of hydrogen peroxide which can be decomposed by 1 c.cm. of blood in the course of two hours is regarded as its "katalase" or "peroxidase" value. Just as the colour index of the blood is the relation of the percentage of haemoglobin to the percentage of red corpuscles, so the katalase index is the relation of the katalase figure to the red corpuscle figure. A high katalase index was found by van Thienen only in pernicious anaemia; in other diseases it was normal or below normal. Tögel and Ceranke have examined 29 cases of pernicious anaemia; in 16 cases the diagnosis was confirmed by autopsy; in 13 the patient is still living. In agreement with the results of van Thienen, they found an increase of the katalase index over 7 only in pernicious anaemia, and they regard it as pathognomonic in this condition, but they did not find it present in all cases. The katalase index might vary considerably within a short space of time in a patient. No prognostic importance could be assigned to the test.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 259. Rare Manifestations of Epidemic Encephalitis.

E. TRÖMNER (*Deut. med. Woch.*, January 16th, 1925, p. 99) has observed about sixty cases of epidemic encephalitis in his hospital during the past three years, and among them there were fifteen with symptoms which have hitherto been seldom or never described. In one case there was a bright red scarlatiniform rash over the chest and back at the height of the attack, when the temperature was 106° F., and the patient was breathing very rapidly. Death occurred early in this case. In another, that of a lad aged 16, the symptoms began with loss of appetite, restlessness, pain in the throat, and diplopia. Delirium ensued, and during convalescence a small-sealed desquamation of the hands and forearm occurred. In another case, that of a man aged 40, the first symptoms were insomnia, slight fever, and diplopia. He was unconscious for three weeks; some time after he had recovered consciousness he was drowsy even by day, and physically and mentally lacking in adaptability. Afterwards his weight increased, and both hands became swollen, the swelling being suggestive of Quincke's oedema. This condition seemed to be permanent and refractory to treatment. The author's list of unusual sequels to epidemic encephalitis includes, in addition to myxoedema of the hands, hominotrophy of the tongue, hemiataxia, and hemiplegia resembling Jacksonian epilepsy. The author records also three cases of epidemic encephalitis with symptoms, including delirium, of a most fulminating character.

### 260. Syphilitic Meningo-myelitis.

B. R. ARIAS (*Rev. med. de Barcelona*, December, 1924, p. 526), who reports a case in a man aged 38, states that syphilitic meningo-myelitis is much more frequent than is generally supposed. As a general rule 10 per cent. of all cases of spinal syphilis run their course in a more or less acute manner. The polymorphous character of spinal syphilis, both in its anatomical and clinical aspects, is so pronounced that there is no diffuse or localized spinal syndrome that it cannot reproduce—such as spinal compression, ascending paralysis, haematomyelia, Erb's paralysis, radiculitis, and disseminated sclerosis. Although syphilis is a frequent cause of paraplegia, being responsible, according to Bazin, for 65 per cent. of all cases of paraplegia, it is very rare to find distinct prodromal symptoms such as backache, more pronounced at night, intermittent claudication, sphincter disturbance, and cerebral symptoms. In the present case there was a sudden onset with loss of power in the legs, accompanied by formation, muscular rigidity, radiating pains in the upper limbs, and slight fever. A diagnosis of syphilitic meningo-myelitis was made, and under treatment by potassium iodide internally in doses of 30 to 60 grains daily and salvarsan intravenously rapid recovery took place. When seen eighteen months later the patient was still in good health.

### 261. Complicated Septic Interlobar Pleurisy.

E. RIST and E. COULAUD (*Bull. et Mem. Soc. Méd. des Hôp. de Paris*, December 25th, 1924, p. 1726) report the case of a girl, aged 18, who was quite healthy until she was knocked down by a taxicab and received scalp wounds on May 18th, 1924. While in hospital she began to cough and to expectorate quantities of fetid pus; no tubercle bacilli were found. A skiagram showed a small hydro-pneumothorax, as large as a mandarin orange, in the middle portion of the left lung. The diagnosis made was septic interlobar pleurisy discharging by a minute communication into a bronchiole. The patient was discharged in three weeks much improved, but six weeks later she returned with a severe cough and pronounced lassitude. The right lung was infiltrated, and the sputum contained tubercle bacilli. In the left interlobar region a faint shadow only was seen in a skiagram. Three weeks later there was a left interlobar fibrosis and infiltration of the upper two-thirds of the right lung; diminished resonance was present and vesicular murmurs accompanied by moist crepitations. The sputum was abundant, without fetor, and there was some fever. The left interlobar fibrosis resulting from the old pleurisy seemed negligible; the principal danger was from the extensive and rapidly spreading tuberculous process in the right lung. Three and a half months after the initial accident a right artificial pneumothorax was performed with complete and immediate relief. Nine days later a skiagram showed real pneumonia of the left interlobar opacity and nine days subsequently this had much

increased. A month later it occupied the middle third of the left lung, there being a central hydro-pneumothorax of 4 cm. diameter. The temperature again rose, and the fetor of the sputum increased. The right pneumothorax and the tubercle bacilli began to disappear rapidly. The danger of leaving the pulmonary tuberculosis to itself while operating on the left interlobar empyema was evident. In view of the fact that the latter had discharged spontaneously it was decided to await further events. Twelve days later all fetor had disappeared, the temperature had fallen, and the patient had gained 7½ lb. The condition steadily improved and only a small opaque triangle in the region of the left hilum remained. The authors inquire whether the interlobar pleurisy has been cured. Tubercle bacilli were no longer found in the sputum, and the patient's condition has remained entirely satisfactory. They add that it is remarkable that at no period of her illness was there any dyspnoea or cyanosis, although respiration was possible only with the left lung, the centre of which was occupied by a septic pleurisy.

### 262. Oedema of the Eyelids in Graves's Disease.

E. ENROTH (*Finska Läkarsällskapets Handlingar*, November-December, 1924, p. 835) refers to oedema of the eyelids as an early and hitherto hardly noticed sign of Graves's disease. It may, indeed, be the earliest sign of this disease, and at first the oedema may be limited to the upper eyelids. Though it is hard and firm its degree varies with the time of day, and it is usually most marked in the morning. It differs considerably from the flaccid oedema of the lower eyelids observed in the subjects of nephritis and heart disease. Although this swelling of the eyelids in Graves's disease is, at any rate to some extent, a true oedema, it may depend partly on an increase of the subcutaneous fatty tissue. The oedema of the eyelids often observed in women during menstruation may, perhaps, depend on factors identical with those concerned in Graves's disease—in other words, the oedema of the eyelids during menstruation may be caused by functional disturbances of the thyroid gland. The author gives details of four cases of exophthalmic goitre in women in which this oedema of the eyelids was demonstrable.

### 263. Lymphangitis following Cutaneous Tuberculin Tests.

IN the course of routine von Pirquet tests with tuberculin in children F. EBERSON (*Amer. Journ. Dis. Children*, January, 1925, p. 29) observed that lymphangitis developed in certain instances. This local manifestation varied in severity and extent and was accompanied by constitutional reactions. Bovine and human tuberculins were used primarily, and in a number of patients tests were made with some of the derivatives of tuberculin: "acetyl O.T." and "ether-insoluble X" substance. Within from twenty-four to forty-eight hours after the cutaneous test a local streak of lymphangitis developed as an extension along the lymph channels of the forearm. The red streak measured from 1 to 5 inches or more in length, and ranged from a limited lateral or medial extension of an indurated and erythematous area to an infiltrated lymphogenous band, which extended upwards on the forearm and beyond the antecubital space to the axilla. Adjacent lymph glands became indurated and definitely palpable, and a rise in temperature of one or more degrees accompanied the reaction. The lymphangitis faded usually within seventy-two hours, and disappeared without treatment after from forty-eight to ninety-six hours. These reactions reappeared when the tests were repeated subsequently in the same patients. The number of children studied was 133; of these, 18 reacted with an associated lymphangitis to cutaneous tuberculin tests; all the 18 had a definite history of exposure to tuberculosis. The symptoms were typical of juvenile tuberculosis; a history of lassitude, loss of weight or failure to gain, chronic "colds," cough or hoarseness, irritability, lack of appetite, profuse sweating of unknown origin, and pyrexial periods otherwise unexplained. Hilum tuberculosis was diagnosed clinically in 12, and tuberculous adenitis with hilum involvement in 4 cases. One patient of the former group developed pulmonary tuberculosis a few months later. In one child an old tuberculous empyema with residual pleurisy was present, and in another Pott's disease was diagnosed. Radiograms demonstrated in every case tuberculous foci in the hilum or intrapulmonary glands. The author suggests that lymphangitis occurring with cutaneous tuberculin tests in children is pathognomonic of tuberculosis with an active focus of glandular origin. In a series of cases of adult tuberculosis the relation of this reaction to focal tuberculosis was similarly confirmed.

264. **Amoebiasis Cutis.**  
L. F. HEIMBURGER (*Arch. Derm. and Syph.*, January, 1925, p. 49) describes a case of amoebic infection of the skin occurring in a Chinaman, aged 39. In the right loin was a large painful ulcerated area, freely discharging brownish putrid-smelling pus. For seven years he had suffered annually from attacks of dysentery. The condition had arisen as an infection of the skin due to the discharge from a sinus leading into a liver abscess, the pus from which contained amoebae. Under daily hypodermic injections of emetino hydrochloride with pulverized ipecacuanha locally for a week recovery rapidly occurred, though previous drastic antiseptic treatment with formaldehyde had not affected the amoebae. Since other cases of amoebic infection of the skin have been reported Heimburger urges that prophylactic measures should be taken after operative treatment of amoebic abscess of the liver.

### Anterior Dislocation of Shoulder.

253. **Anterior Dislocation of Shoulder.**  
W. W. PLUMMER and F. N. POTTS (*Journ. Bone and Joint Surg.*, January, 1925, p. 190) describe an operation for recurrent anterior dislocation of the shoulder. Anterior internal slipping of the head of the humerus is prevented by fascial transplants to the anterior and external aspect of the joint in order to increase the rigidity of the capsule. Two narrow six-inch strips of fascia lata from the thigh are threaded at each end on to a full curved needle. Through an incision from the top of the acromion to below the surgical neck of the humerus the capsule is bared; the needle on one end of the first strip is passed through all the layers down to the bone at the base of the greater tuberosity, and is then directed upwards toward the anterior tip of the acromion, where it is passed through a drill hole in the edge of the acromion so as to bring the edge of the fascial strip upon the upper surface. The needle on the other end is inserted at the base of the greater trochanter a little external to the first suture and brought up through the acromion, where the two ends are drawn tight and sewn together. The second fascial strip is similarly implanted external to the first, thus producing two fascial transplants to the capsule in the form of two double mattress sutures. Excellent results have followed this operation in two cases, and it is recommended for its simplicity and for the useful range of motion resulting.

266. Gonorrhoeal vesiculitis.  
E. ROUCAÏROL (*Journ. d'Urol.*, December, 1924, p. 466) points out that infection of the vesiculæ seminales during an attack of gonorrhoea is not at all uncommon. It may appear spontaneously, or follow injections or urethral lavage. The acute form with pain and frequency is only transitory and yields to medical treatment, but the gonococcus itself remains in the vesiculæ and frequently indicates its presence by causing discharge. Many different methods of treatment have been adopted, with uncertain results. It appears that the gonococcus, as in other parts of the urethra, does not remain on the surface but burrows into the crypts, where it has to be followed if it is to be effectively destroyed. Roucaïrol has successfully treated by diathermy several cases which had resisted other forms of treatment. The urethral electrode is maintained in position for twenty minutes at a temperature of 45°C. Where the patient cannot tolerate this a rectal electrode is used; this is usually borne more satisfactorily. Fourteen cases successfully treated by this method are recorded; the number of treatments ranged from about four to fifteen to obtain certainty of a cure.

267. *Surgical Treatment of Exophthalmic Goiter.*  
D. PRAT (*Bull. et Mém. Soc. Nat. de Chir.*, January 17th, 1925, p. 17) describes the results obtained in the treatment of exophthalmic goitre in the clinic of Professor Lamas. Medical treatment is first tried, including rest combined with sedatives, cardiac tonics, and appropriate feeding. If the symptoms are improved this method is continued. In the majority of cases, however, the patients are in an advanced state of the disease, and medical treatment is employed simply to improve their chances at operation. In cases exhibiting the typical syndrome with enlargement of the thyroid, exophthalmos, tremors, and tachycardia, a hemithyroidectomy is usually performed. If this does not prove sufficient, the superior thyroid artery to the remaining lobe is ligatured. In cases with marked symptoms sympathetomy is advised, and perhaps also ligature of one or more of the thyroid arteries. Regional anaesthesia is always employed, using 1/2 per cent. novocain and adrenaline, and Kocher's collar incision is found the most satisfactory. When performing the operation of sympathetomy both the superior

and inferior cervical ganglia are removed with the intervening chain. In a series of thirty-two cases treated by the different operations outlined above there was one death—a mortality of 3 per cent. One case was treated by radium. The conclusions reached are that medical treatment combined with x rays may be tried for three to six months. If the condition does not improve no time should be wasted and the patient should then be transferred to the surgeon whilst in good condition for operation.

263. **Adenitis in Gastric and Duodenal Ulcer.**  
H. FLÖRCKEN (*Zentralbl. f. Chir.*, January 3rd, 1925, p. 13), who in June, 1923, drew attention to the significance of enlarged lymphatic glands in the region of the stomach in the diagnosis of gastric ulcer, states that from January 1st, 1923, to October 1st, 1924, 196 undoubted cases of gastric and duodenal ulcer were operated on in the surgical clinic of St. Mary's Hospital, Frankfurt, and that 118, or 57.8 per cent., had shown enlargement of the glands in the gastric area. The adenitis was commonest in cases of ulcer of the lesser curvature, in which it was present in 71.2 per cent., and least frequent in duodenal ulcer, in which it was found in only 48.6 per cent. The involvement of the glands is, he thinks, to be attributed either to inflammation directly connected with the ulcer or to gastritis accompanying the ulcer. The absence of adenitis in gastric or duodenal ulcer may be due to absence of inflammation in the region of the ulcer, as in the case of a cicatrix, or to the absence of an associated gastritis. But as this gastritis occurs in 100 per cent. of all cases, according to the investigations of the Tübingen Pathological Institute, it would be more correct to make constitutional factors responsible for the absence of adenitis. Flörcken points out that enlarged glands in the region of the stomach do not always indicate gastric disease. Apart from general infectious, such as syphilis, which frequently cause glandular enlargement, cholecistitis often gives rise to adenitis of the gastric glands without anything abnormal being found in the stomach. Flörcken concludes that if enlarged glands in the gastric area are found in a patient with a history suggestive of gastric ulcer resection is advisable in the absence of any other cause for the adenitis, especially if there has been any considerable haemorrhage.

269. **The Surgery of Jaundice.** p. 287) polts  
J. B. DEEVER (*Annals of Surgery*, January, 1925, p. 287) polts  
out that many cases of jaundice are not medical conditions,  
and that their relief can only be obtained by surgical means.  
The surgeon may recognize three pathogenic types of jaundice:  
one due to obstruction, the second to excess and perverted  
haemolysis, and the third, or post-operative type, due to  
infection or operative trauma. It may also be divided into  
two clinical groups—painful and painless jaundice. The  
common types of jaundice are due to gall stones, cancer of  
the head of the pancreas, and cholangitis. Deaver tilks  
that in jaundice due to cholangitis, and not to calculous  
obstruction, anastomosis of the gall bladder to the duodenum  
is perhaps the best operative procedure. Where there is a  
non-traumatic stricture of the common duct he prefers dilata-  
tion of the stricture and the introduction of a T-tube. He  
adds that in cases of bile-duct injury the upper end of the  
duct must be exposed by careful dissection. When the ends  
of the duct cannot be brought into apposition it is best to  
anastomose the proximal end with the duodenum, either  
with or without the aid of an introduced catheter. The  
post-operative dangers to the jaundiced patient are hepatic  
insufficiency and bleeding. The latter can be controlled by  
calcium chloride injections, but the former may prove fatal in  
spite of fluids and glucose. The author gives a warning that  
no operation should be performed if the urine contains  
acetone and diacetic acid. When the common duct is cut  
across, it is best repaired at once and sutured over a T-tube;  
this gives satisfactory bile drainage. In a case of jaundice,  
Deaver remarks, the surgeon can never be called too early,  
but he can be called too late. The operative treatment  
depends finally upon the cause of the jaundice, and may  
consist of drainage of the gall bladder or the common duct;  
if an anastomosis is indicated the author thinks that  
cholecysto-duodenostomy is probably the best procedure.

276. **Post-operative Pneumonia.**  
H. FEATHERSTONE (*Brit. Journ. of Surgery*, January, 1925, p. 487) comments on the frequency of post-operative pneumonia, and the importance of care in selecting an anaesthetic and in its administration. He dismisses considerations of age and sex as being of minor importance, but emphasizes the fact that the general health and any prior disease of the lungs are matters of moment. Attention is drawn to the fact that post-operative pneumonia is often not recognized if the attack is mild or abortive. The paths of infection are stated as the blood stream, aspiration, and lymphatic infection through the right half of the diaphragm. Apart from cases

of acute sepsis, post-operative pneumonia usually follows operations on the abdomen, especially its upper segments. Pain in the abdomen, he finds, is a contributing factor, causing rigidity of the abdominal wall and a reflex inhibition of the diaphragm and intercostal muscles. This interferes with lung expansion and favours collapse.

#### 271. Ureteral Stricture.

G. L. HUNTER (*Amer. Journ. Obstet. and Gynecol.*, January, 1925, p. 47) states that stricture of the ureter is much more frequent than is commonly supposed, both in males and females, and is often overlooked as a cause of chronic or recurrent abdominal pain. He accepts as the chief etiological factor infection from distant foci in teeth, sinuses, tonsils, cervix uteri, appendix, gall bladder, or elsewhere. He believes that as a result of acute inflammation or congestion an old-standing stricture may quite suddenly become narrower and lead to severe colic, and denies that stricture is necessarily accompanied by gross dilatation above, or that gross changes in the urinary tract due to stricture need cause symptoms. Ureteral stricture is usually bilateral. Bladder symptoms occur in two-thirds of the cases and in one-third rank as the chief complaints. The urine contains pus in 20 per cent. of cases (pyelitis, infected hydronephrosis, or pyococcirosis); in 50 per cent. suspicious signs occur, such as a trace of albumin, an occasional cast, a few leucocytes, or erythrocytes. Severe haematuria is not very common. Usually there is renal tenderness and undue sensitiveness of the ureter either as it crosses the pelvic brim one inch to the side and below the navel or near the entry to the bladder. The diagnosis is clinched by the passage of a wax-built catheter along the ureter or by radioscopic examination.

### Therapeutics.

#### 272. Autoserum Therapy by Cantharides Vesication.

THIS old but little used method has been revived by PAOLO IACCHIA (*La Pediatria*, January 15th, 1925, p. 89). The technique is simple and easy. The skin is cleaned with alcohol and a cantharides blister, 1½ to 2 inches wide, is applied and left for twenty-four to thirty-six hours. The blister is then emptied by aspiration with a sterile syringe and the contents injected subcutaneously. In children the site of vesication should be the front of the chest or thighs so as to avoid losing fluid if the blister be torn, otherwise it is preferable in the vicinity of the most acute lesion so as to take advantage of the local action of the cantharides. Twenty-one children, of ages 6 to 7 years, were treated by this method. Iacchia concludes that its effect is immediate and striking in rheumatic infections with effusions (polyserositis, polyarthritis, etc.), but does not prevent the onset of endocarditis. It is useless in tuberculous lesions, and of transitory or doubtful benefit in other conditions such as arthritis of unknown origin, osteitis probably gonococcal, and prurigo. The experiments were performed in the absence of other specific treatment. When the autoserum was effective Iacchia found that the results were most marked; he recommends, however, simultaneous treatment by salicylates if there is any suspicion of the onset of endocarditis. He thinks that the autoserum acts partly through a protein reaction, partly by bacterial vaccination, and partly by its serum effects, with a possibly stimulating action of the cantharides on the production of antibodies. He has not observed any ill effects on the kidney.

#### 273. Sodium Citrate as a Haemostatic.

ENCOURAGED by the success of Hofmeister and Nenbauer in the treatment of haemophilia by intramuscular injections of sodium citrate, M. RENAUD (*Journ. de Thérap. Française*, December, 1924, p. 185) has used this salt in a variety of haemorrhagic conditions. Cases are reported of cancer of the rectum, cancer of the pharynx, early and late tuberculosis, menorrhagia, and metrorrhagia, where one injection generally secured relief from haemorrhage for some weeks or months. The action of the citrate was most marked in the case of neoplasms. The author recommends the intravenous injection of 15 to 30 c.c.m. of a 30 per cent. solution in water of the citrate. The solution is not stable, and should be freshly prepared at the time of injection. The injection causes a certain intoxication, as evidenced by a sensation of distress and malaise, pallor, rapid and weak pulse, headache, and pyrexia. This reaction was always transitory, and never of such a degree as to cause the slightest anxiety; it may be lessened by the simultaneous injection of cardiac tonics, such as sparteine and quinidine.

#### 274. Malarial Treatment of Progressive Paralysis.

S. DONNER (*Finska Läkarsällskapets Handlingar*, January, 1925, p. 8) gives an account of 40 cases of progressive paralysis treated with malaria in the course of a year in an asylum in Finland. It was found that though this treatment was most suited for early cases some patients responded very well to it, although the disease had lasted more than a year. While patients likely to die in a few months in the natural course of events were not, as a rule, considered suitable for this treatment, the necessity for keeping the succession of malaria parasites unbroken was such that reserving this treatment for early cases was not always feasible. From 2 to 5 c.c.m. of defibrinated blood was injected subcutaneously, and though the original strain of parasite was tertian its subsequent behaviour was in several cases that of quotidian fever. In certain cases the disease behaved like tertian and later like quotidian fever in the same patient. The longest incubation period was twenty-one days and the shortest five days, the usual period being one of six to twelve days. The temperature often exceeded 104° and in most cases was over 102°. In a few cases there was an afebrile interval between the attacks, and in 2 cases the malarial infection died out spontaneously. In order to make the treatment as thorough as possible the infection was not terminated by the administration of quinine till there had been several bouts of fever; in more than half the total number of cases over ten bouts of fever, each exceeding 102°, were allowed to run their course before quinine was given. In 10 cases from twelve to sixteen bouts of fever were permitted. The bouts soon ceased after the exhibition of quinine, and there were no relapses of the malaria. Of the 30 patients whose treatment dated far enough back to warrant drawing conclusions as to its efficiency, 9 were restored to complete working capacity, 4 were able to resume light work, and 5 were well enough to return to their homes or to take up light work in the asylum. There remained 9 who were not improved, and 3 who died, the causes of death being cancer in one case, an intradural haemorrhage in the second, and rapid progress of the paralysis in the third. The author's opinion of the value of this treatment is definitely favourable.

#### 275. Manganese Cacodylate in Neurasthenia.

G. LEMOINE (*Journ. de Thérap. Française*, December, 1924, p. 177) places on record the favourable results he has had with manganese cacodylate in the treatment of that vague group of symptoms termed neurasthenia. He does not claim to have found a specific remedy, but asserts that he gets hotter results more rapidly than with any other therapeutic agents. Such results were rise in blood pressure, increase in motor power, return of appetite, and improvement in digestion, leucocytosis, particularly of eosinophil cells, increase of urea excretion, and diminution of ethereal sulphates and indican in the urine. The sensation of mental and physical weakness progressively diminished and the patient began to feel better and to take again a healthy interest in life. The author has used the drug in five cases of melancholia with similarly favourable results. Manganese cacodylate, prepared by saturating pure cacodylic acid with pure manganese hydrate, is soluble and is administered hypodermically. The dose is not stated.

#### 276. Antiseptic Dyes in Surgery.

W. TÜRSMID (*Zentralbl. f. Chir.*, February 14th, 1925, p. 352) states that during the last two decades the idea of the utilization of the so-called dye antiseptics has received considerable attention in surgical literature; Banmann, Römer, Hoffmann, and others have published the results of their experimental work. In 1917 Banmann published the statistics of the use of two aniline dyestuffs as antiseptics in over 1,000 cases in Payr's clinic at Leipzig and Kirschner's clinic at Königsberg. The results were surprisingly good, but the best were obtained by the use of methylene blue, and subsequently of methyl violet (pyocyanin ceruleum, Merck). This was employed in three forms: (1) crystalline powder, (2) aqueous or alcoholic solutions, (3) gauze impregnated with the dyestuff. The results obtained were most satisfactory. Stilling and Wortmann in their bacteriological investigations drew attention to the high antiseptic value of these dyestuffs. Römer, Gebb, and Lohlein, by means of experiments extending over many years, investigated the bactericidal power (*in vitro*) of fifty-eight aniline dyestuffs, testing their action on pyogenic micro-organisms and other pathogenic bacteria. Some of these dyestuffs, though possessed of distinct bactericidal power, were definitely injurious to tissue cells, and in certain cases produced extensive necrosis. Türsmid has used pyocyanin 10 600 cases; the results were very satisfactory, often even astonishing. He first employed a 10 per cent. aqueous solution of pyocyanin, then Römer's Greifswald dyestuff mixture, and latterly 10 per cent. and

5 per cent. alcoholic solution of pyocetanin, for painting the wound, in the form of bandages, as an instillation in deep wounds, or by the use of dressings of gauze previously saturated in the dyestuff solution. All these preparations were equally successful in the treatment of compound fractures, abrasions, lacerations, and contusions, and also as dressings after surgical operations. In two cases of erysipelas a fall of temperature and rapid healing followed the application of the solution of pyocetanin to the inflamed area. In furunculosis and paronychia the results were equally satisfactory.

#### 277. Protein Therapy in Venereal Diseases.

L.-M. BONNET and PÉTOURAUD (*Lyon Méd.*, January 11th, 1925, p. 29) refer to Bonnet's former articles on the injection of boiled milk in the treatment of buboes and of gonorrhoeal orchitis. In addition to ordinary milk, some writers have recommended milk more or less modified, and also solutions of casein, but there is no evidence that those preparations are superior to ordinary milk. The authors have, however, experimented with them because, although ordinary milk is very active, it has certain disadvantages. A marked general reaction occurs frequently; there is usually some amount of painful swelling at the site of injection; and finally, there is the trouble of preparation (filtration and boiling). During the last six months they have treated all suitable cases by casein injections; the number of patients was 18 and they received in all 62 injections. The preparation selected was a 10 per cent. solution of casein peptone (soluprotine). The authors give clinical details of their 18 cases (17 males and 1 female). Of the males 15 had acute epididymitis or orchitis, which was unilateral in 14; in 2 cases, after apparent cure, the other testis became inflamed, but the inflammation subsided quickly after a second course of injections. The female patient had Bartholinitis and painful inflammation of the adnexa: two injections (each of 1 c.cm. of soluprotine) relieved the pain rapidly. The remaining male patients (2) had: (a) Soft sores on penis and scrotum accompanied by a large red, but not suppurating, hubo. After two injections of 1 c.cm. of soluprotine, the adenitis disappeared in eight days. In (b) there were multiple syphilitic chancre with severe bilateral inguinal lymphadenitis. After the first injection (1 c.cm. of soluprotine) there was a marked reaction—rigors, sweating, and pyrexia of 103° F. In two days pain had disappeared, and the swelling was much diminished; four days after the first injection all inflammation had disappeared, the adenitis was typically syphilitic, and the patient commenced a course of neosalvarsan. The authors employed hypodermic or intramuscular injections, as the intravenous method appeared to be unnecessary. At first they used only 0.25 c.cm., but now they give 1 c.cm. at the first injection and 2 c.cm. at the second; they recommend that these be given on alternate days. Some patients received only two injections; the majority had four or five. The injections were usually well tolerated; two patients had evening temperatures after their first injection, but this did not recur after the second injection. One patient had six injections for orchitis without reaction; orchitis then developed on the other side thirty-eight days after the first injection; he had rigors, profuse sweating, and a temperature of 103° F. after an injection of 1 c.cm. of soluprotine. This was apparently due to sensitization by the first series of injections and subsequent anaphylaxis.

## Anaesthetics.

#### 278. Acetylene Anaesthesia.

H. WIELAND (*Brit. Journ. Anaesthesia*, January, 1925, p. 142) considers that acetylene-oxygen anaesthesia is likely to supersede chloroform and ethyl chloride-ether anaesthesia in many operations, as it has the advantage of greater safety. It is administered through an airtight mask from an apparatus specially designed to permit accurate percentages of acetylene and oxygen mixture being given. Commencing with a mixture of 70 to 80 per cent. of acetylene with 30 to 20 per cent. of oxygen, sensation to pain disappears after a few breaths have been taken, and consciousness is lost in from one to five minutes; the concentration of acetylene should then be diminished and be continued at 40 to 50 per cent., or even less, throughout the operation. Consciousness is regained in about two minutes after removal of the mask. Retching and vomiting are said to be rare, and the subjective sense of comfort afterwards may be marked, patients frequently asking for food within a quarter of an hour of recovery. No serious

sequoia appear to have occurred, and the method is of wide application even in conditions in which other general anaesthetics are contraindicated. Its disadvantages are its inflammability and liability to explosion, though only the former is to be feared if a special anaesthetizing apparatus is used; open fires and electric sparks must be avoided, and the electro-cautery should not be used near the mask. Abdominal rigidity cannot always be overcome, and the addition of small amounts of ether may be necessary. Other observers have reported that in low concentrations of about 10 per cent. labour pains are eliminated without loss of consciousness or diminution of the force of the uterine contractions.

#### 279. Regional and Field Block Anaesthesia.

C. F. EKENBARY and M. LANGWORTHY (*Journ. Bone and Joint Surg.*, January, 1925, p. 47) consider that the value of regional or field block anaesthesia in operations on the limbs is not sufficiently appreciated. They point out that whereas extensive bone operations are very liable to cause shock, in none of the cases treated by such anaesthesia did any shock occur. Novocain was used exclusively and was administered by the methods of Braun, Labat, and others; Ekenbary and Langworthy claim that it is effective and may be safely given to patients of all ages (except young children) for whom a general anaesthetic might be risky. Their report of 164 regional anaesthetics covers almost every type of operation on the extremities. Out of 38 brachial plexus blocks the anaesthesia was perfect in 37, one only requiring gas during fracture manipulation; and of 51 sciatic and internal saphenous blocks the anaesthesia was perfect in 48. Four combined sciatic, external femoral cutaneous, anterior crural, and obturator blocks were all perfect, while in 71 field blocks 70 were perfect as regards anaesthesia. It is not claimed that this method should supplant other anaesthesia, but merely that it has a definite usefulness in many cases.

#### 280. Syphilis as a Complication in Anaesthesia.

E. R. LECOUNT and H. A. SINGER (*Journ. Amer. Med. Assoc.*, January 31st, 1925, p. 358) record two cases in which syphilis of the brain appears to have been the cause of death in connexion with general anaesthesia. They suggest that the evidence indicated that the anaesthetic and the operative shock were insufficient to explain death, and that syphilitic changes in the brain rendered both patients susceptible to sublethal doses of morphine and ether. They recall the conclusion of Lillie that the essential feature of the change produced in narcosis or anaesthesia of the normal individual is reversibility, the cells of the body regaining their normal properties and functions at the conclusion of the anaesthesia, regardless of the depth of unconsciousness produced. Concentration of the anaesthetic agent beyond a certain degree caused cytolytic or irreversible changes and consequent death. The present authors suggest that a decrease in the limits of reversible change is observable in several conditions, including the atherosclerosis of diabetes and states of lethargy or coma. They believe that such a limitation occurs in cerebral syphilis, and that therefore, when any symptoms or signs are present suggesting some morbid condition of the cerebral nervous system, a thorough examination to exclude syphilis ought to precede any surgical operation.

#### 281. Spinal Anaesthesia.

D. A. ORTH (*Amer. Journ. Surg.*, Anaesthetics Supplement, January, 1925, p. 2) considers spinal anaesthesia to be of distinct value for operations below the costal arch. By administering apothecary with adrenaline and giving a subcutaneous injection of 3 grains of caffeine citrate one hour before the operation, followed by 1 grain every hour for six doses after the administration, circulatory and respiratory depressions are anticipated and avoided. The method is best tolerated by old people and should, according to Orth, cause no more discomfort than a hypodermic injection. Since no preliminary preparations are necessary he thinks it is an ideal anaesthetic in emergencies, while the production of anoci-association renders it of value in operations likely to produce much shock. Orth points out that in intestinal surgery spinal anaesthesia has the advantage of producing complete relaxation of the abdominal wall while the involuntary muscles of the intestines are contracted. He adds that haemorrhage is noticeably less, and that post-operative retching and straining are absent. In a small number of cases it may be necessary to supplement with ether, but the author says that when such is the case only a small amount of ether is required, and that the relaxation is more complete than in general anaesthesia.

## Obstetrics and Gynaecology.

### 182. Tubal Rupture and Abortion.

ACCORDING to A. RIOTTE (*Bull. Soc. d'Obstét. et de Gynéc.*, 1925, 1, p. 120), there are exceptions to the rule that in ectopic pregnancy tubal abortion generally leads to gradual hæmorrhage with formation of a pelvic hæmatocoele, while rupture of the tube generally gives rise to profuse bleeding extending to the general abdominal cavity and producing acute anaemia and collapse. Apart from the cases in which the secondary rupture of a hæmatocoele leads to peritoneal innudation, or a tubal abortion is accompanied by a concealed rupture, cases occur in which at operation for acute hæmorrhagic peritoneal innudation the gravid tube is found unruptured, but either empty as result of abortion through the osium abdominale, or with the ovum in process of extrusion there. Three illustrative cases are related, in two of which the tube was found empty and notably flaccid at the site of implantation of the gestation sac. The explanation of the acute hæmorrhage in these cases is thought to lie in a situation of the ovum at the extreme outer end of the tube, so that the tube wall is unable to limit for a time the bleeding.

### 233. Hemiplegia in the Puerperium.

A. FRUHNSHOLZ and A. FRANÇAIS (*Gynéc.*, 1925, xi, 1, p. 13) distinguish the following forms of hemiplegia and aphasia occurring after childbirth. (1) Hemiplegias due to a morbid condition, whether organic or functional, not connected with childbirth, such as those occurring in syphilitic, arterio-sclerotic, or hysterical subjects. (2) Hemiplegias associated with morbid conditions connected with pregnancy or labour—as, for example, in eclampsia, or endocarditis following puerperal sepsis. (3) A special clinical type, the "hémipégie des accouchées." Of the last-named type, as the result of a study of twelve cases, the following description is given. It is more common in young and in primiparous patients, and almost without exception there has been some abnormality of pregnancy, or labour, or both—toxaemia, instrumental delivery, or precliptate birth. It may appear as early as the third day or as late as the third week. The onset is sudden, and in the large majority of cases the right side is affected. Jacksonian epileptic attacks are relatively common; sensory symptoms are less prominent than motor. The prognosis is good, a fatal termination being quite exceptional; complete functional recovery is the rule. Many cases have been regarded as hysterical, but the authors believe the pathological explanation to be the deposit in the brain of small emboli derived from the pelvic veins. They suggest that persons having a patent foramen ovale may be particularly prone to this accident, and refer to such a finding made at autopsy after cerebral and pulmonary emboli in the puerperium. Crural phlebitis occurred in two of their cases.

### 284. Urinary Incontinence in Women.

F. K. TE WATER NAUDE (*South African Med. Record*, December 13th, 1924, p. 536) discusses the etiology and treatment of urinary incontinence occurring during pregnancy or labour. He considers that that form which occurs towards the end of pregnancy is caused by the drawing upwards of the region of the trigone while the urethra and neck of the bladder remain stationary, thus causing overstretching and consequent inefficiency of the sphincter muscle. As preventive measures he advocates pushing back the anterior vaginal wall and the vulval portion lying immediately below the symphysis during and throughout each expulsive pain, with, if necessary, an episiotomy to ease tension. During the early puerperium regular two-hourly micturition should be insisted upon in order that the over-stretched parts may recover their tone. If the condition still persists at the end of six weeks resort to operation is advised to narrow the cross-section of the urethra, either by manipulating the tube itself (Albarran's method), by a purse-string suture, or by an operation aiming at restoration of the fascial sling. In very recalcitrant cases the operation devised by Göbel and Stoeckel, in the author's experience, gives the best results.

### 285. X-ray Treatment of Cancer of the Uterus.

H. WINTZ (*Deut. med. Woch.*, January 2nd, 1924, p. 19) prefaces a long statistical paper with the remark that during the past eight years there have been improvements every year in the technique of the x-ray treatment of carcinoma of the uterus at Erlangen. His statistics deal with 800 cases, which are classified according as the disease involved the upper or the lower segment of the uterus and was operable

or inoperable on admission to hospital. With regard to the injurious effects of x-ray treatment, there were only 6 cases, observed in the period 1915-23, in which the fatal issue could be traced to the treatment; with improvement in technique such fatal incidents should, he thinks, become very rare. Of the 18 cases of carcinoma of the lower segment of the uterus treated in 1915 (operable and inoperable cases) only one passed the test of survival five years later, whereas this was the case with 22 of the 97 cases treated in 1920. This improvement was the more significant as the proportion of operable cases coming for treatment had been greatly reduced since 1915. In this year 57 per cent. of all the cases were operable, whereas in 1920 only 10.5 per cent. were so. With regard to the patients treated in the operable stage, it was found that of those treated in 19.0 75 per cent. of the patients who suffered from carcinoma of the lower segment of the uterus were still well in December, 1924, and this percentage was as high as 88.8 for the patients who in 1920 had suffered from carcinoma of the body of the uterus. As for the inoperable cases, 15.3 per cent. of the patients suffering from carcinoma of the lower segment of the uterus were still well at the end of 1924 after a five-year observation period. When the moribund were excluded from the inoperable cases, the percentage of recoveries after a five-year interval was 19.6. The author concludes that x-ray treatment may fall completely in 15 to 20 per cent., even in cases seeming to be early and favorable, and in spite of carefully graduated treatment; he admits that some of the defences of the body against carcinoma are still unknown.

### 286. Radium Treatment of Carcinoma of the Cervix.

J. HEYMAN (*Surg., Gynecol. and Obstet.*, February, 1925, p. 161) reviews the results obtained at Stockholm between 1914 and 1921 of radium treatment of cervical carcinoma. Three treatments with radium salt were given in each case, the second one a week after the first, and the third three weeks after the second. At each treatment radium was introduced into the uterine cavity and packed against the tumour surface in the vagina for about twenty-two hours. The sum of the three treatments was about 2,400 milligram element hours in the uterus and 4,500 in the vagina. A heavy filtration was used equivalent to 2 mm. of lead in the uterus, and 3 to 4 mm. in the vagina. The combined use of x rays and radium has been abandoned, it being found that better results were obtained from the use of radium only. The mortality due to peritonitis or sepsis was only 6 in 505 cases. Of 181 inoperable cases clinical healing resulted in 30, and persisted for at least five years. Of the remaining inoperable cases nearly 20 per cent. were free from symptoms three years after beginning the treatment. In the majority of patients treated, even though complete cessation of symptoms was not obtained, a more or less lasting improvement resulted. Heyman points out the importance of realizing the limitations of this form of treatment and of employing a carefully planned technique. He remarks that in the hands of the inexperienced radium treatment involves great risks without any chance of securing results comparable with those of surgical operations.

### 287. Torsion of a Normal Fallopian Tube.

P. R. MICHAËL (*Nederl. Tijdschr. v. Geneesk.*, December 6th, 1924, p. 2828) records a case in a married woman, aged 47, the mother of one child, in whom torsion of an otherwise normal Fallopian tube with a long mesosalpinx was mistaken for acute appendicitis, the true diagnosis being only established by laparotomy. Menstruation took place on the third day after operation. Michaël remarks that cases of this kind are exceedingly rare, and that it is much more frequent for torsion to arise in connexion with adnexa which have been infected or are the site of new growths. The only other examples of torsion of an undoubtedly normal Fallopian tube known to Michaël are two cases reported by Smith and Butler in 1921, in both of which there was also a distinct connexion with menstruation. In one case there were always attacks of pain in the hypogastrium one or two days after cessation of menstruation, while in the other a violent attack of abdominal pain preceded menstruation by five days, and after slight diminution became aggravated on the appearance of the monthly period. On operation the mesosalpinx of the left Fallopian tube, which had undergone torsion, was twice as long as that on the right side. Histological examination of the Fallopian tubes in both cases showed nothing abnormal. As there were no adhesions, tumour formation, hernia, or any external cause for torsion in Michaël's case, but only an abnormal mobility of the tube due to a long mesosalpinx and circulatory disturbances caused by premenstrual hyperaemia, Michaël is of opinion that the conditions for torsion required by Payr's haemodynamic torsion theory were fulfilled.

## Pathology.

### 288. The Cause of Dyspnoea.

J. MEAKINS (*Canadian Med. Assoc. Journ.*, January, 1925, p. 2) discusses the different modes of production of dyspnoea, and stresses its value in diagnosis, prognosis, and treatment. Accepting the definition of dyspnoea as "the consciousness of the necessity for increased respiratory efforts," he remarks that although this consciousness is always referred to pulmonary function, yet the cause of dyspnoea may be situated actually in some far distant part of the body. It is necessary, therefore, to distinguish between pulmonary and coelular respiration, either or both of which may be concerned in dyspnoea. Meakins points out that the chemical regulation of pulmonary respiration depends upon the hydrogen-ion concentration in the tissues. If this is increased pulmonary action will be augmented, and vice versa; this is due to change in the relative acidity or alkalinity of the arterial blood and the tissues, which depends mainly on the carbon dioxide content. The hyperpnoea of exercise is due to increased metabolism, and in conditions where such increase occurs during rest—as in fever and increased thyroid activity—the point at which dyspnoea is produced is reached at a much earlier stage than in health. The incomplete elimination of acid ions in renal insufficiency disturbs the acid-base balance and gives rise to hyperpnoea, soon followed by dyspnoea. Treating the renal disturbance will cure the dyspnoea, and temporary improvement in respiratory distress follows the introduction of hydroxyl ions in the form of sodium phosphate or sodium bicarbonate. Interference with the elimination of carbon dioxide causes a somewhat analogous dyspnoea, which may be due to a chronic structural abnormality such as emphysema, tumour of the lung, or thickened pleura, or to some acute lesion such as pulmonary oedema or the early stage of pneumonia. In such conditions as emphysema the carbon dioxide partial pressure of the inspired air is greatly increased; this is compensated by an increase in the alkali reserve and by polycythæmia, which prevent the hydrogen-ion concentration of the blood and tissues from being much altered. The tissues can also accustom themselves to diminished partial pressure of oxygen, and so a moderate amount of work can be performed in such a disease as acute oedema. Meakins points out also that if the partial pressure of oxygen of the inspired air is sufficiently increased the oxygen will penetrate any alveolar exudate present and so reach the blood. He strongly urges, therefore, the use of oxygen in the early stages of pneumonia with a view to helping the patient through the subsequent period of consolidation, when the bacterial toxæmia becomes so important. He discusses the dyspnoea occurring in other conditions, including cardio-vascular disease, when the degree of dyspnoea is directly related to the severity of circulatory insufficiency, the probable cause of the dyspnoea being the relative slowness of the circulation through the tissues in proportion to the metabolism. He adds that it has been found that a decrease in the vital capacity of the lungs occurs in circulatory failure, as a result probably of the decreased expansibility of these organs owing to their capillary engorgement.

### 289. Essential High Blood Pressure and Kidney Function.

F. KISCH (*Wien. Arch. f. inn. Med.*, October 15th, 1924, p. 30) records his observations on renal function tests in 90 cases of paroxysmal high blood pressure in women at the climacteric period, in 7 cases in men, and in many cases of permanent high pressure. He emphasizes the importance of estimating the indican in the blood in this connexion. In cases of pronounced paroxysmal high pressure he found usually that the renal functions were normal; but in some chronic cases changes in the renal functions were detected. In permanent high pressure he always found impairment of the renal functions. W. Falta and his colleagues have asserted that in cases of permanent high pressure, pathological changes in kidney arterioles and in the glomeruli are always found. Kisch concludes that under certain constitutional conditions paroxysmal increase, or marked fluctuation of blood pressure may occur unassociated with any kidney lesion—for example, in the climacteric period in women. From paroxysmal high pressure, especially when long persisting or pronounced, kidney lesions may develop before the pressure becomes permanently high; the resulting impairment of the renal function is usually unimportant. He adds that paroxysmal high pressure passes very often into permanent high pressure and that in cases of permanent high arterial pressure a marked degree of impairment of the kidney functions is almost always found. This may not be very marked, but it can be detected by careful investigation. In agreement with the conclusions of W. Falta and G. Herzheimer, permanent essential high pressure is regarded by Kisch as an indication of a lesion of the arterioles of the kidney.

### 290. Classification of the Haemolytic Streptococci.

P. DURAND and P. SÉDALLIAN (*C. R. Soc. de Biologie*, January 30th, 1925, p. 157) report the results which they have obtained in their endeavour to classify the haemolytic streptococci by means of agglutination and the absorption of agglutinins. Dealing first with direct agglutination, they find that the test is frequently impossible to perform owing to the difficulty of obtaining a homogeneous suspension of the organisms. In about half the cases in which it is possible to perform the reaction the results obtained were similar to those given by the absorption test; in the other half the results were such as to preclude their use for purposes of classification. The agglutinability of the streptococci is liable to great variation; for no apparent cause a given strain which has previously been agglutinated to a high titre by a given serum will become inagglutinable—even in cases in which the serum has been prepared from the strain in question. Moreover, of two strains of streptococci isolated from the same patient, the one will be constantly agglutinated, the other will refuse to agglutinate. There are certain strains which the authors describe as "madly agglutinable"; they are characterized by their tendency to react with several serums of quite different types. Such vagaries as these falsify any classification based on direct agglutination, which gives results sometimes incomplete, sometimes doubtful, and sometimes apparently contradictory. On the other hand, they find that the absorption of agglutinins is a much more precise method, enabling the type of the organism to be ascertained with a considerable degree of certainty. In the case of the "madly agglutinable" organisms it gave quite clear-cut results; these strains, though agglutinated by numerous serums of diverse types, can absorb the agglutinins from the serums of only one type. Using this method they were able to classify 84 strains out of 130 into six types, comprising respectively 36, 23, 9, 6, 6, and 4 strains. Within any one type they found a variation between the different members; some seemed to possess a more complicated antigenic structure than others. Serums prepared against these complex strains could be absorbed by only a few strains, whereas serums prepared against strains of simple antigenic structure were absorbed by a large number of strains. The criterion they adopt for the delineation of their types is the existence in common by all the members of it of some antigenic constituent. In rare cases they found certain strains which contained antigens common to two types; these strains were able to absorb the agglutinins from serums of both types. Somewhat at variance with their classification into six types, they conclude by saying that the streptococci may be arranged, according to the structure of their antigen, in the form of a genealogical tree with confused branches, whose nodes are occupied by the strains possessing the most complex structure.

### 291. Vaccination against Scarlet Fever.

C. ZOELLER (*C. R. Soc. de Biologie*, February 6th, 1925, p. 242) has tested the possibility of rendering susceptible subjects immune to scarlet fever by vaccinating them with a filtered broth culture of *Streptococcus scarlatinae*. The ten individuals on whom the tests were made were first given an injection of toxin in a dose of 0.3 c.c.m.; after eight days a second injection was made of 0.6 c.c.m.; the third injection of 1.2 c.c.m. was given after a similar interval. These doses of toxin corresponded roughly to 150, 300, and 600 Dick doses—the term he uses for the minimal reacting dose as determined by intradermal injection into a susceptible subject. After two injections of toxin two of the subjects had become Dick-negative. After three injections on seven subjects, two had become Dick-negative, one gave a doubtful reaction, and the remaining four were still strongly positive. From these results it is seen that though the injections of toxin gave rise to no ill effects, their efficacy in producing an active immunity in the subjects tested was quite irregular. In another paper in the same journal (p. 244) the author records his attempts to produce an anatoxin—that is, a modified toxin retaining its antigenic immunizing properties, but devoid of toxicity—similar to the one prepared by Ramon in the case of diphtheria toxin. A plain peptone broth culture filtrate was used; to it varying quantities of formal were added, and it was then placed in the incubator at 38° C. for thirty days. After different periods it was tested for toxicity by intradermal injection into susceptible subjects. Briefly, it was found that a concentration of formal of 0.25 per cent. produced no effect, that one of 0.5 per cent. had an attenuating action, and that one of 1 per cent. so diminished the toxicity that even when injected in a dilution of 1 in 10 it failed to give rise to a local reaction. By the use of this last preparation it would be possible for immunizing purposes to inject as many as 1,500 to 2,000 Dick doses, but whether it would exert the desired immunizing action—whether, in fact, it is a true anatoxin—has not yet been determined.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 292. The Normal and Pathological Venous Pulse.

L. BARD (*Journ. de Méd. de Lyon*, January 20th, 1925, p. 31) believes that the venous pulse, which first attracted attention about the middle of the last century, is destined to hold a much more important position in future cardio-vascular pathology. He points out that it is the only source of information about the progress of the returning blood and the conditions under which it enters the right auricle and ventricle. Grapho tracings show changes in volume which produce five principal waves, of which two are negative: these indicate an acceleration due to auricular and venous diastole. The three positive waves are due to transient stasis ("succussion waves"), and, in exceptional cases, entirely to a true regurgitation. The first positive (presystolic) wave is due to auricular contraction; the second (systolic) shows the convection of a succussion due to closure of the auriculo-ventricular valve; the third (according to some writers systolic, to others diastolic) is actually complex. The first part—late systolic—arises entirely from the conduction of secondary waves from the ventricular wall and from the conditions under which the auricle is filled. The second part—early diastolic—is caused by the sudden elevation of the interauriculo-ventricular septum, which occurs immediately the ventricle relaxes. A small intersystolic wave and supplementary diastolic waves may be seen. In the various arrhythmias the timing of the several waves together with the length of the intervals indicate on the tracings sinus arrhythmia, extra-systoles, heart-block, and other abnormalities. Moreover, in bradycardia, an examination of the tracings suffices to indicate the origin of the greater part of the arrhythmias, thanks to the abrupt rise of the auricular wave of the venous pulse, also of the superposition of auricular and ventricular systoles. Enfeebled contraction of the right side of the heart, whether due or not to tricuspid incompetence, is indicated by systolic stasis followed by prediastolic collapse. In severe anaemias there is an exceptional intensity of the venous pulse, which extends to the inferior vena cava, and occasionally to the femoral veins. The volume of the diastolic wave produces an oscillation of the jugular veins comparable to that of the carotids in aortic regurgitation. Hypertrophy of the left ventricle of renal origin is shown by the accentuation and prolongation of the presystolic wave, which reveals the "crossed-hypertrophy" of the left ventricle and right auricle. Bard adds that our knowledge of the diastolic waves is still incomplete, and hitherto the electrocardiograph has thrown but little light upon this aspect of cardiology.

### 293. Ulcerative Bronchitis due to Vincent's Organisms.

CHEVALIER JACKSON (*Journ. Amer. Med. Assoc.*, December 6th, 1924, p. 1845) records two cases which are remarkable for the fact that they are the first on record in which the bronchial lesion of infection with Vincent's organisms has been observed with the bronchoscope. The first patient was a girl, aged 18, in whom Vincent's angina, at first mistaken for diphtheria, had persisted for nearly a month. The correct diagnosis was made by finding Vincent's bacilli and spirilla, and under local application of tincture of iodine, silver nitrate, and other agents, the faucial lesion entirely disappeared in a few weeks. The temperature, however, remained high and there was a slight leucocytosis. A cough developed, with offensive and blood-stained sputum. A great variety of râles were heard on both sides of the chest, and the percussion note was impaired at the bases. Bronchoscopy showed ulceration of the mucous membrane of the right and left bronchi. Specimens of pus and shreds of whitish material were taken with forceps, and on examination showed numerous Vincent's organisms. Applications of 20 per cent. silver nitrate were made on six subsequent bronchoscopies at weekly intervals, and complete recovery took place. The second case occurred in a man, aged 22, who had been sent to Jackson's Bronchoscopic Clinic with the diagnosis of abscess of the left lung, due to aspiration of a tooth. The sputum, though scanty, was very foul. Physical examination showed diminished expansion of the left chest, and numerous râles, especially on the left side, with an impaired percussion note over the lower lobe. No foreign body was found on bronchoscopy, but tube-shaped casts were removed from the left bronchus, leaving ulcerated surfaces of the mucous membrane. Examination of the casts showed a predominance of Vincent's organisms,

in addition to streptococci, pneumococci, and saprophytes. The patient did not return for treatment, but the condition cleared up in about a month's time after he had gone to sea.

### 294. Diabetic Coma complicated by Renal Insufficiency.

In reviewing the literature on diabetic coma E. WARBURG (*Acta Med. Scand.*, Fasc. iv-v, 1925, p. 301) draws attention to the three clinical groups into which cases are placed according as coma, heart failure, or respiratory peculiarities predominate. He adds a fourth group, with renal insufficiency, and describes four cases in which the patients were admitted into hospital in deep coma, had high blood sugar, relatively low glycosuria, no ketones in the urine, albuminuria absent or in small degree only, and marked urea concentration. In two cases the respirations were not typically hyperpnoeic, the diuresis at first was small but increased under treatment, and the patients recovered. In the other two cases the respirations were of the typical Kussmaul variety; 1,000 to 2,000 c.cm. of urine was passed in the first twenty-four hours, but gradually the diuresis entirely failed. The autopsies in these two cases showed an acute parenchymatous nephritis in one case and macroscopic evidence of acute kidney degeneration in the other. All four cases were treated on the same lines—injections of "diasulin" (stated by the makers to contain in one unit three Toronto units), subcutaneous injections of physiological salt solution, and of stimulants such as camphor and caffeine. The author has collected several cases in the literature that belong to this group, and stresses the importance of treating coma cases early and energetically with heart tonics and diuretics in order to avoid cardiac and renal complications.

### 295. Prognosis in Treated Congenital Syphilis.

E. LENSTRUP (*Ugeskrift for Læger*, January 29th, 1925, p. 104) traces the careers of the first 100 infants treated for congenital syphilis in a Weiland Home in Denmark. This institution was opened in the summer of 1916, and has already received 167 syphilitic infants. The treatment consisted of repeated courses of mercurial inunction, each of thirty applications, such courses being separated by intervals of two months. Some of the patients were also given salvarsan. They were kept in this institution for many years, and of the first 100 admitted it was found that 22 had died, 13 were imbecile, 28 were backward in various ways, and only 37 could be regarded as normal in every respect. Many of the deaths were due to influenza and its complications, and in no fewer than 18 cases death was due to bronchopneumonia. All the deaths occurred under the age of 3 years, and as many as 13 under the age of 1 year. Of the 18 infants whose mothers had been given specific treatment before they were confined, as many as 12 were normal, while there were only 3 backward children—1 who was imbecile and 2 who died. Lenstrup adds that these figures clearly show that the intrauterine treatment of an infant suffering from syphilis is of great importance. He suggests that considerable improvement would be effected if this Weiland Home could accommodate the infants' mothers for half a year in order that breast-feeding might obviate the perils of artificial feeding.

## Surgery.

### 296. Phlebäarteriectasia.

F. SONNTAG (*Zentralbl. f. Chir.*, January 10th, 1925, p. 66), who records an illustrative case in a man aged 51, defines phlebäarteriectasia as a progressive dilatation of an arterial area, including the capillaries and veins. Its origin is apparently spontaneous. It is probably congenital at first and due to defective development of the vascular region concerned. The increase in size usually takes place slowly, though it varies somewhat in different cases. The condition is rather uncommon as Sonntag has found only about a dozen cases on record, and has seen only two other cases besides the present one—in a man aged 49 and a girl aged 16. Of eight cases collected by Bockenheimer half were between the ages of 40 and 50. Males are more frequently affected than females, in the proportion of 5 to 1. Both sides are involved with equal frequency, and the arms are more frequently the site of the lesion than the legs. The condition usually first develops in the hand and then spreads upwards. The most striking feature is the dilatation of the arteries,

and to a less extent of the veins. Other symptoms which have been noted in the literature and were present in Sonntag's case were: (1) A telangiectasis in the form of a small bluish-red patch on the back of the hand. (2) Cutaneous anomalies, including bluish discoloration, hypertrichosis, and hyperhidrosis. (3) Increase in circumference of the arm. (4) Distinct rise of local temperature. (5) Elongation of the forearm by 3 cm. (6) Slowing of the pulse by 18 beats through compression of the artery. Complications such as ulceration, infection, haemorrhage, and necrosis were absent in the present case. In some cases, including Sonntag's patient, the prognosis is favourable, but in others the course of the disease is rapid, and may lead to destruction of the limb and death of the individual. Treatment in most cases should be conservative at first. Many patients suffer little inconvenience for several years, so that they do not seek medical advice. When the lesion increases in size, and the skin becomes thinned, so that there is a danger of haemorrhage or infection, operation is advisable. Little can be expected from ligature or electrolysis, and resection of the dilated vessels is usually required, as in Sonntag's case, in which a good result was obtained. Amputation of the upper arm has had to be performed in several cases owing to severe pain, haemorrhage, or necrosis.

### 297. Arterio-sclerotic and Thrombo-angitic Gangrene.

L. ELOESSER (*Deut. Zeit. f. Chir.*, December, 1924, p. 95) states that gangrene of the lower extremities, especially of the toes, is a more frequent cause of admission to hospital in San Francisco than in Germany, as is shown by the fact that there were 77 examples of this kind among about 3,000 surgical cases admitted to the surgical department of Stanford University in the period 1920-24. The gangrene in these cases was usually due to one of three causes: (1) senile arterio-sclerosis, (2) juvenile arterio-sclerosis, (3) thrombo-angitis or Buerger's disease. Eloesser maintains that in all three forms of gangrene expectant treatment is best, disarticulation of the toes being performed if necessary. If conservative treatment fails, disarticulation should be performed at the knee-joint, especially in senile gangrene and the progressive form of thrombo-angitis. Periarterial sympathectomy, which was carried out in 10 cases of vascular disease of various kinds, had no effect.

### 298. Recurrent Dislocation of the Shoulder.

G. VALTANCOLI (*La chir. degli org. di movim.*, December, 1924, p. 131) states that next to the lower jaw the shoulder-joint is most subject to recurrent dislocation. The condition, which is not very uncommon, was known to Hippocrates and Paulus Aegineta. Seidel in 1918 collected 117 cases in which operation had been performed, and estimated that about 30 cases had been reported which did not undergo operation. Valtancoli gives the following statistics of 16 cases observed among 15 patients at the Rizzoli Orthopaedic Institute of Bologna University from 1900 to October, 1923, among 140 traumatic dislocations of the shoulder-joint. In 14 patients the dislocation was unilateral and in only one bilateral, though not always so, as the dislocation on the right side after that on the left. As is the rule in the male sex is much the most frequently affected, only one of the 15 cases being in a woman. In like manner, of 83 cases collected by Seidel in which the sex was stated, 66 were males and only 17 females. The condition is most frequent in early adult life: 11 of the 15 cases occurred between 21 and 25, and the remaining 4 at 17, 18, 30, and 39; none occurred in childhood. Of 76 cases reported by Seidel, 41 were between 21 and 30, and none was under 17. In 10 of Valtancoli's cases the condition set in after a traumatic dislocation, and the first recurrence took place in a time varying from a few days to six months. In 2 cases the condition developed during an epileptic attack, and in the remaining 3 the trauma, if it could be regarded as such, was insignificant. In every case the recurrence of dislocation was extremely frequent on the slightest effort. One patient had as many as seventy dislocations in the course of three months, and in another dislocation of the posterior type could be performed at the patient's will without causing him much pain. In 15 cases the dislocation was anterior, and in only one posterior (of the subacromial type). The anatomical lesions in recurrent dislocation of the shoulder have been classified by Seidel as follows: (1) rupture of the capsule, either alone or in association with other changes in the joint (the most frequent lesion); (2) rupture of the muscles, especially the external rotators (a not uncommon lesion); (3) detachment and fracture of the head of the humerus; (4) fracture of the glenoid cavity, either alone or in conjunction of the head of the humerus or glenoid cavity. Of Valtancoli's 15 patients 13 were treated surgically, while 2 refused operation and were provided with a protective

apparatus. The type of operation in each case was capsulorraphy preceded by arthrotomy. No immediate bad results were obtained in any case. In 9 cases which were followed up 6 made a complete recovery, one sustained another dislocation six months after operation as the result of an injury, in one the operation was a failure, as the patient had several recurrent dislocations in the course of the year, and in the last case no recurrence took place for seven years, when, as the result of injuries received in the war, repeated dislocations occurred.

## Therapeutics.

### 299. Sequelae of Neo-arsphenamin Treatment.

C. M. SMITH (*Arch. Derm. and Syph.*, February, 1925, p. 237) reports a case of severe bleeding and purpura following the administration of neo-arsphenamin. A man, aged 44, received two courses of arsphenamin intravenously with mercury intramuscularly—twenty-four injections in all. After the twenty-third injection saltness occurred together with bleeding from the nose and gums and purpuric spots in several places; these conditions quickly disappeared. Profound collapse, cyanosis, and general weakness followed the twenty-fourth injection, with more severe bleeding from the nose, gums, rectum, and the intramuscular needle puncture. The bleeding lasted for three or four days, and the purpura which followed lasted for two weeks. The patient was not haemophilic. On the sixth or seventh day the blood picture was essentially normal. Some areas of periostitis on the right tibia and radius improved under iodide and mercury, and his general health improved with iron citrate and quinine. His Wassermann reaction remained positive, and he developed ulcerative lesions on the tonsils and at the base of the tongue. Treatment was directed towards improving his general health prior to a resumption of antisyphilitic treatment.

### 300. Subarachnoid Injections in Neuro-syphilis.

G. MARINESCO and S. DRAGANESCO (*Presse méd.*, January 31st, 1925, p. 130) observe that although some writers have reported a certain improvement in a few cases of tabes dorsalis and of general paralysis of the insane after intravenous or intramuscular injections of arsenobenzol, mercury, or bismuth, it must be admitted that generally the results of treatment of neuro-syphilis by these methods have been disappointing. It is now recognized that the anatomical arrangement of the cerebro-spinal blood vessels renders the introduction of more than an infinitesimal quantity of any therapeutic agent very difficult. Sieard hoped to overcome this difficulty by the administration of small repeated doses, but Akatsu and Noguchi have proved that the tolerance of the spirochaete towards salvarsan and mercury increases rapidly under the administration of progressive doses of either drug. Gennerich believes that ordinary antisyphilitic treatment, in arresting the process of generalized infection, diminishes the progress of immunization and permits the spirochaetes to invade the meninges and the cerebro-spinal fluid, where they escape from the action of medicaments carried in the general blood stream. Inflammatory processes lessen the permeability of the pia mater and the cerebro-spinal fluid penetrates the subjacent parenchyma of the brain or spinal cord, carrying with it the spirochaetes. In general paralysis spirochaetes are very numerous and penetrate to the deeper layers of the cortex, but they are absent from the membranes and meningeal vessels. The failure of ordinary antisyphilitic treatment is shown conclusively by the fact that while minute quantities of arsenic have been recovered after death from the cortical grey matter, neither mercury nor bismuth has been found there nor in the cerebro-spinal fluid, and many other writers have shown that the subarachnoid injection of salvarsanized cerebro-spinal fluid. In three cases of general paralysis a remission of symptoms persisted for more than a year. Gennerich has introduced an ingenious modification of the technique of subarachnoid injection. He abstracts a large quantity (50 to 120 c.cm.) of cerebro-spinal fluid, to which neosalvarsan is added. In this way he obtains a very high dilution of salvarsan, which is not irritant to the cord, and, also, elevation of the burette containing the salvarsanized cerebro-spinal fluid carries the fluid upwards towards the brain. Gennerich also performs a double lumbar puncture in other cases—(a) at the level of the interval between the first and second lumbar vertebrae; and (b) between the fourth and fifth lumbar vertebrae. The patient is placed on the table, lying on his side. Two needles, rubber tubes, and burettes are employed in the double puncture. Through the lower needle 50 to 90 or 100 c.cm. of fluid is drawn off into the attached burette. The salvarsanized fluid is prepared and is reintroduced through

the upper needle, which is then withdrawn and the patient's head and shoulders are depressed below the level of his feet. In this position the burette attached to the lower needle is elevated, and at least one-half of the cerebrospinal fluid contained in this burette is permitted to re-enter the spinal canal. By this manoeuvre the concentrated salvarsanized fluid is carried towards the brain and is at the same time diluted by the larger quantity of fluid reintroduced through the lower needle. Either of these methods may be employed repeatedly. The results hitherto recorded have been far more satisfactory than with the older methods: lymphocytosis disappeared and in several cases the Wassermann reaction became and remained negative. In a group of 17 general paralytics, 6 returned to their employment, 5 showed a satisfactory improvement, 2 have had a short remission of symptoms, followed by a serious relapse, and in the remaining 4 cases the result of intracranial injection was almost nil. Among the 6 patients who returned to work, 4 were able to remain at work, 2 were capable of some useful work, but all showed signs of mental deterioration. Of 2 tabetic patients one improved greatly, the clinical symptoms disappeared, and the Wassermann reaction became negative. In 3 tabetics with incontinent optic atrophy, marked improvement occurred in one case, but in the others, which were of longer duration, there was little improvement.

### 301. Sodium Salicylate in Epidemic Encephalitis.

R. BENARD, MARCHAL, and Y. BUREAU (*Bull. et Mém. Soc. Méd. Hôp. de Paris*, January 16th, 1925, p. 61) record a case of epidemic encephalitis in a woman, aged 23, which assumed the form of severe febrile chorea with ptosis, paralysis of convergence, salivorrhoea, ties of respiration and expectoration, and albumin and excess of sugar in the cerebro-spinal fluid. No effect being obtained by intravenous administration of urotropine, intravenous injections of sodium salicylate in 10 per cent. solution of glucose were employed. After the first injection of 0.50 gram of salicylate the temperature fell from 102.4° to 98.6° F. without any other change being noted. Subsequently a daily injection of 1 c.cm. was given without any effect until the fifth day, when improvement set in and rapid recovery took place.

## Radiology and Electrology.

### 302. X-ray Examination of the Spinal Cord.

J. BERBERICH and S. HINSCH (*Klin. Woch.*, January 1st, 1925, p. 14) describe the method of x-ray examination of the spinal cord which they have employed during the last eighteen months. Lumbar puncture is performed with the patient in the lateral position. After measuring the pressure, 5 to 10 c.cm. (or more if the pressure is high) of the cerebrospinal fluid is allowed to flow away. Then 4 to 6 c.cm. of Merck's iodipin solution is introduced under very slight pressure. The opening of the cannula is directed towards the patient's head, the lateral position of the patient being maintained, and raising the pelvis is recommended. The x-ray photograph may be taken at convenience afterwards; but raising of the pelvis is necessary for some time previously. By this method the heavy iodipin solution gravitates within the spinal dura mater and the whole extent of the spinal cord is indicated in the photograph. To overcome certain technical difficulties two modifications are made. For the detection of changes in the upper part of the spinal cord suboccipital injections are employed. A second modification is the combination of the injection of iodipin and air. After lumbar puncture and removal of a little cerebro-spinal fluid as already described, only 2 c.cm. of iodipin is injected at first, and then under slight pressure 15 to 30 c.cm. of air is injected, and finally the rest of the iodipin. In this way, if the horizontal position of the body be maintained, a column of air is seen in the x-ray photograph, limited by iodipin, both at the end towards the cervical region and also at the end towards the sacrum. By this method meningeal tumours, carious bone invasion, localized meningitis, etc., may be detected. In twenty cases this method has been employed and no bad effects have followed.

### 303. Dangers of Large Doses of X Rays at Short Intervals.

A. GUNSETT (*Journ. de Radiol. et d'Électrol.*, November, 1924, p. 481) thinks that it is now generally recognized that the three German axioms—(1) employment of deeply penetrating rays and of a zinc filter of at least 0.5 mm. in thickness; (2) application of the "causticide" dose (*Karsinomedosis*) based on the erythema dose; and (3) application of this dose at one sitting—are impracticable, since the erythema dose cannot be determined accurately. The theory of a "cancer-

indling" dose is described as biological nonsense, and the dose is said to be ineffectual in the majority of cases. German authorities, with few exceptions, still endeavour to give a maximal dose at one sitting, but Gunsett states that even in Germany the expected results do not appear to have been obtained. The French practice has been to spread the treatment over a period of eight days. Gunsett also criticizes the practice of giving small doses, and suggests that they may have a harmful effect and stimulate the growth of a tumour. Laborde states that if large doses of x rays can cause degeneration and death of cells, feeble irradiation can, on the contrary, produce a stimulation of nuclear division, which has been observed in experiments on the lower animals, on plants, and also in man and the smaller mammals. Gunsett gives details of many of these experiments on germinating seeds, eggs of protozoa, frogs, and hens, as well as observations on the effect of large and small doses on tumours in men and animals. He concludes: (1) The dangerous effects of large doses given at short intervals are indisputable and are admitted generally even by those who practise that method. These dangers are both local (on the tumour) and general (on the patient's system). (2) The stimulating effects of small doses of x rays have not been proved definitely, either in plants, on animals, in normal tissues, or in experimental cancer or in human cancer. The observations that seem to prove this stimulating effect on human cancer are capable of another interpretation.

### 304. Diathermy in Pharyngeal Cancer.

D. MCKENZIE (*Brit. Journ. Radiol.*, January, 1925, p. 9) advocates diathermy in the treatment of both eradicable and inoperable pharyngeal cancer. Its value lies in its double action—upon the diseased tissues, and upon the surrounding tissues. In dealing with the primary deposit should be removed by diathermy and the lymphatic glands by combined dissection and diathermy, the intervening tissues being treated by diathermy puncture. While this can be done at one sitting McKenzie thinks it is better to divide it into two separate operations. In inoperable conditions bold and wide diathermy of tissue will prolong life, and the glands after diathermy puncture may shrivel and disappear. Although it must be admitted that diathermy may encourage malignant growth, yet the fact that its action is both destructive and actively germicidal renders such a result less likely than after treatment by other methods. In post-ericoid carcinoma diathermy may be applied by means of a blunt terminal, but since it is difficult to estimate the depth of the charring produced McKenzie considers that radium is to be preferred as a palliative.

## Obstetrics and Gynaecology.

### 305. Treatment of Placenta Praevia.

ON account of the numerous articles which have appeared lately in obstetrical literature regarding the value of the various treatments of placenta praevia, and especially the position of Caesarean section in such cases, G. CONRAD (*Zentralbl. f. Gynäk.*, January 31st, 1925, p. 275) discusses fully the statistics of 203 cases of placenta praevia treated at the Virchow Hospital during the years 1905-24. It is noted that primiparae were far more liable to the condition than is generally supposed—20.2 per cent. of the cases being first pregnancies. Nearly 60 per cent. of cases occurred in the first, second, or third pregnancy. In regard to age, 53.2 per cent. occurred between the ages of 30 and 40, it being as common in the late thirties as in the early; 58.6 per cent. of the cases were partial or lateral in type and 41.3 central. The total foetal mortality at birth and within fourteen days of birth was 54 per cent., 48.3 per cent. being stillborn, and of these 44.1 were premature. The proportion of viable to non-viable children was 159 to 50. The maternal mortality was 2.8 per cent. (18 cases), the cause of death being anaemia from bleeding in 10 cases; the other causes were sepsis 3, peritonitis 3, and pulmonary embolism 2. The classical Caesarean section was performed 51 times, with a maternal death rate of 5 (9.8 per cent.) and a foetal mortality also of 5; one foetus was premature. In 5 cases the lower uterine segment method was employed with no maternal or foetal deaths. In 43 cases mifeuerynters were used, followed by version and extraction, with a maternal death rate of 5 (11.6 per cent.), but with a mature foetal death rate of only 16.3 per cent. Bipolar version was performed in 40 cases, with only 3 maternal deaths (7.5 per cent.), but the foetal mortality was 50 per cent. There was pyrexia in the puerperium of 18.2 per cent., and in 11.3 per cent. the placenta was adherent. In his summary up Conrad recommends the lower uterine segment Caesarean section because it seems to

give a small maternal mortality; in support of this he quotes other statistics. There is also said to be less likelihood of a morbid puerperium, but he qualifies this recommendation by saying that before Caesarean section the condition of the mother, the viability and health of the child, the position of the placenta, and the cleanness of the case must all be taken into account. In the cases not suited for such treatment bipolar version is advised as being the best treatment for the mother. Conrad concludes by saying that the right place for the treatment of a placenta praevia is the hospital.

305. VON MIKULICZ-RADECKI (*Arch. f. Gynäk.*, December 15th, 1924, p. 245) describes the treatment at Kiel during twelve years of 168 cases of placenta praevia. A sharp distinction is drawn between the lines on which it is desirable to treat cases in private practice and in hospital. In private practice, it is stated, the object of therapy must be to save the maternal life with little regard to that of the child. The private practitioner is only concerned, therefore, with (1) rupture of the membranes, in cases of vertex presentation with partial placenta praevia and uterine contractions present; (2) version when the os admits two fingers; (3) cervical dilatation when the os is smaller. In the subsequent stages of labour he should renounce measures which are in the interest of the child alone, such as the Smellie-Velt grip, which entails danger of a torn and infected cervix. In a hospital, on the other hand, other principles must regulate the treatment, and the foetal life must be considered as well as that of the mother; active means of accelerating birth are therefore permissible and desirable. Version and the insertion of dilating bags have in this clinic been associated with high foetal mortality, and since 1918 have been largely replaced by Caesarean section, with a striking improvement in the foetal mortality and no increase of maternal deaths. It is concluded that Caesarean section is the method of choice for delivery in cases in which the child is living, the placental insertion completely or almost completely covers the os, and no infection appears to be present.

307. Testing Patency of Fallopian Tubes.  
I. C. RUBIN (*Journ. Amer. Med. Assoc.*, February 14th, 1925, p. 486), as the result of the investigation of 1,000 consecutive transuterine insufflations to test tubal patency, considers that the most suitable time for the test is the fourth to the seventh day after the cessation of the last regular menstrual period. He finds that the endometrium is then relatively quiet and the mucosa is at its thinnest, offering the least obstruction to the introduction of the uterine cannula. No risk of there being a uterine or extrauterine pregnancy is incurred, and the theoretical possibility of endometrial dislocation or gas embolism is eliminated. Rubin remarks that clinical and experimental observations indicate that a pressure of 200 to 250 mm. of mercury should not be exceeded in the test, though higher pressures may be employed by experienced hands in order to open tubes that have been previously demonstrated to be closed.

## Pathology.

308. The Pathogenesis of Cancer.  
L. W. SANBON (*Journ. Trop. Med. and Hygiene*, February 2nd, 1925, p. 39) advances evidence in support of a parasitological cause for cancer, and quotes the discovery by Börrer that the larval form of the thick-necked tapeworm in the cat could originate sarcoma in the liver of the rat. Fibiger of Copenhagen later associated sarcoma of the stomach of the rat with a round, striated muscle of the larva of which he named "necplasticum," the parasite among the striated muscles of the rat in a Danish sugar refinery. He adduces a considerable amount of other evidence on these lines, and is convinced that parasitic worms have some definite connexion with the production of malignant disease, but that the actual essential cause is some ubiquitous organism—probably a filter-passer—which only thrives in tissues of lowered resistance. In support of his views incriminating cockroaches he gives a detailed account of his epidemiological and parasitological investigations in Iceland and Italy.

309. A Method of Diagnosing Whooping-cough.  
E. BEST (*Arch. f. Kinderheilk.*, December 24th, 1924, p. 93) has recently employed the method adopted by Chiewitz and Meyer at the Copenhagen Serum Institute for the early diagnosis of whooping-cough by growing the Bordet-Gengou bacillus on a medium composed of glycerin-potato agar and defibrinated blood. She found, however, that it was not only

an extremely laborious and lengthy method, but was by no means reliable when the results were negative. She also emphasizes the fact that the naked-eye appearance of the colonies is by no means sufficient for the diagnosis of *B. pertussis*. In the cases of suspected whooping-cough suddenly developing in a clinic the practical value of this method will be limited even in the most favourable circumstances, since the preparation of fresh media and the growth of the colonies require several days.

## 310. Gonococcal Infectivity.

J. F. HOGAN (*Journ. Amer. Med. Assoc.*, January 17th, 1925, p. 194) urges the need of a more systematic attempt to prevent gonorrhoeal patients from being released from treatment until cure is established. He lays stress on the value of cultural tests in this connexion. The medium he recommends for obtaining gonococcal cultures is testicular agar, to which gentian violet has been added in the proportion of 1 in 200,000 to 1 in 500,000 parts. In this way gonococcal colonies were protected from being overwhelmed by staphylococcal growth. After massage of the prostate and vesicles the first drops of prostatic secretion were ignored and a later drop collected in a glass pipette introduced into the meatus; the secretion is then expelled on to the warm agar slant. Pinpoint colonies of gonococci were obtained in some cases after forty-eight hours, but it was frequently necessary to allow a week or more to elapse. He records ten cases in which this method was satisfactorily employed, even though in some cases the discharge was scanty and smears appeared to contain no gonococci. He therefore points out that the examination of smears ought not to be considered as establishing a cure in chronic gonorrhoea. The infectivity in this disease is, he thinks, of longer duration than previously believed, the organisms having been found in some cases as long as three or four years after an acute attack. He considers three negative cultural examinations essential before releasing the patient, each taken at intervals of a month, during which no treatment has been given.

## 311. Pseudo-valvular Formations in the Heart.

A. FABRIS (*Chore e Circolazione*, December, 1924, p. 441), who records three illustrative cases, states that two distinct types of pseudo-valvular formations may be found in the human heart. The first is found on the left surface of the inter-ventricular septum or between the trabeculae of the apex. The second type is found on the endocardium, and should be regarded as due to a hyperplastic reaction of the serous membrane to the mechanical stimulus of the blood stream, and perhaps also as the result of local endocarditis. In the author's first case, in which death was due to asphyxia from laryngeal stenosis, the autopsy showed a fibrous pocket, with its opening below like a swallow's nest, on the left surface of the inter-ventricular septum. The subjacent endocardium showed a slight uniform thickening. In the second case, which occurred in a child aged 1 year who had died of bronchopneumonia, a small pocket was also found on the left surface of the inter-ventricular septum one-fifth of an inch from the aortic orifice. In the third case, which occurred in a man aged 20 who had died of mitral incompetence, multiple pseudo-valvular formations were found in the left auricle.

## 312. Experimental Epilepsy.

W. E. DANDY and R. ELMAN (*Bull. Johns Hopkins Hosp.*, January, 1925, p. 40) endeavoured to determine whether localized traumatism of the brain rendered cats more susceptible to convulsions and whether the site of the injury had any important bearing on the production of the convulsions. A 10 per cent. emulsion of wormwood oil (of which absinth is the active principle) was administered through a stomach tube several weeks after a brain lesion had been produced by cortical and subcortical extirpation, simple incisions into the brain substance, or the embedding of a small foreign body locally below the cortex. The authors found that one-third to one-seventh of the dose of absinth required to produce convulsions in normal cats would excite attacks when the motor cortex had been injured several weeks previously. Injuries to the cerebellar and occipital lobes were found to be much less effective in producing susceptibility to convulsions than were injuries to the motor cortex. A minimal convulsive dose produced unilateral convulsions without loss of consciousness, and with a stimulant of just the right dosage the seizure remained focal as in petit mal, but an increase in the stimulant caused general convulsions. In normal cats restlessness and irritability preceded the convulsions, but in those with healed motor defects such preliminary irritability was absent.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 313. The Peripheral Forms of Epidemic Encephalitis.

L. BÉRIEL and A. DEVIC (*Lyon méd.*, January 25th, 1925, p. 112) describe a new form of epidemic encephalitis which does not appear to have been isolated before, and does not in any way resemble the ordinary forms of the disease. The virus in these cases seems to attack exclusively or principally the peripheral motor and sensory neurons, and the affection appears to correspond to a meningo-radiculo-neuritic process. The onset may be sudden, the patient becoming paralytic within a few hours, or it may take a few days to develop. Painful symptoms may occur at this stage. At the height of the disease the affection presents the ordinary phenomena of polyneuritis, but the most striking feature is the widespread character of the paralysis, which often involves the sphincters, upper limbs, and sometimes even the face, although this distribution bears no relation to the intensity of the motor defect. Pressure on the nerves and muscles is generally painful. On the other hand, no anaesthesia was ever noted. Lumbar puncture shows that a meningeal reaction is almost constant. The course of the disease was always favourable, and the patients recovered completely without any paralysis or atrophy. The authors remark that this is a very important fact, because the great difficulty in diagnosis is to eliminate the painful forms of acute poliomyelitis. At the onset the diagnosis will depend partly on the intensity of the general symptoms, which is usually less in polyneuritis than in poliomyelitis, although there is no absolute rule. The most important element, however, in the diagnosis is the much wider diffusion of the paralysis in polyneuritis and especially the persistence of this widespread paralysis. Whereas in poliomyelitis certain groups of muscles rapidly recover their normal function, while others undergo a rapid atrophy, in polyneuritis there are only slight differences in the impairment of the various muscle groups affected and the atrophy is always the same—late in development and of very slight degree. The diagnosis is nevertheless usually difficult at first, and the authors have often had to wait several weeks until a localized atrophy or complete recovery decided the nature of the case.

### 314. "Illness of Infection" in Measles.

E. W. GOODALL (*Clin. Journ.*, February 11th, 1925, p. 69) states that during the thirty-two years that he has been medical superintendent of a fever hospital he has seen seven or eight examples, of which he records four, in which a child exposed to the infection of measles a few hours earlier has developed symptoms strongly suggestive of an attack of measles, such as slight rise of temperature, sneezing, conjunctival injection, and even a morbilliform rash, but the symptoms have disappeared in a few hours or a day or two. At the end, however, of a period within the limits of the incubation stage of measles the patient developed an undoubted attack of the disease. Goodall is of opinion that the first symptoms may have been due to the process of infection. The only other disease in which he has seen such a condition is enteric fever, but the enteric cases may be explained by a double simultaneous infection. Goodall finds it difficult, however, to accept the explanation that such a double infection occurs in measles producing the symptoms described, because the symptoms are those of measles and not of measles together with some other disease.

### 315. The Blood Picture in Small-pox.

G. PANTASIS (*Schweiz. med. Woch.*, December 25th, 1924, p. 1189) records his observations on the blood picture in small-pox during an epidemic at Berne in the years 1921-23. His conclusions are as follows: (1) In the prodromal stage there is a leucopenia; in severe cases during the eruptive stage and later there is a leucocytosis of about 10,000. In a certain number of cases during the pre-eruptive stage there is a leucopenia which gradually becomes replaced by normal values or even leucocytosis as the eruption develops. In some cases the leucopenia persists in the eruptive stage and is not converted into leucocytosis until the stage of desquamation. (2) Leucopenia in the prodromal stage is due to diminution in the absolute number of the polymorphonuclear cells, while there is an absolute increase in the number of lymphocytes. (3) Leucocytosis in the eruptive stage is due to an absolute increase in the number of the lymphocytes, while the polymorphonuclear cells show subnormal or barely normal values. In severe cases the absolute number of the

polymorphonuclear cells in the stage of suppuration may exceed that of the lymphocytes. (4) While, apart from toxic changes in the nuclei, the polymorphonuclear leucocytes show no special morbid forms, large lymphocytes and irritation forms appear and at the end of the prodromal stage constitute 20 per cent. of the total number of leucocytes. They are numerous in the eruptive stage and are still present in the stage of desquamation. (5) Large mononuclears and transitional forms are reduced in number absolutely and relatively during the early stage, but later may be normal in amount. (6) The eosinophils are reduced in number at the onset, especially in severe cases, but in a later stage are normal in amount, and in mild cases may even be increased. (7) The red corpuscles show no changes worth mentioning. (8) Pantasis's observations essentially agree with those of all other writers who have studied the blood picture in classical small-pox. (9) According to Pantasis's experience the blood picture in mild small-pox is the same as in severe small-pox and varicella, so that examination of the blood is of no value in distinguishing variola from varioloid or varicella. (10) On the other hand, the blood picture may be of some value in differentiating small-pox in the prodromal stage, and even in the eruptive period, from other infectious diseases, especially as hardly any other disease is characterized by the early appearance of a lymphocytosis.

### 316. Late Serum Immunization in Measles.

J. C. REGAN (*Journ. Amer. Med. Assoc.*, November 29th, 1924, p. 1763) records his observations on fifteen children in whom the course of measles was modified by injection of convalescent's serum late in the incubation period—namely, between the sixth and ninth days—in doses from 8 to 10 c.c.m. The modifications in the disease were as follows: (1) The incubation period showed a definite tendency to be longer. (2) The invasion was shortened. (3) Coryza was either absent or mild. (4) Koplik's spots were usually absent. (5) The exanthem was lacking. (6) Prodromal rashes occurred with greater frequency. (7) The eruption was altered in being either scanty or atypical, and in most instances by becoming ecchymotic as it faded. (8) The temperature curve was distinctly lower. (9) The constitutional reaction was decidedly less pronounced. (10) Complications were practically lacking. Regan believes that with the exception of institutional cases and of children under 2 years of age or older children suffering from debilitating diseases, the late immunization of susceptibles is by far the most logical procedure.

## Surgery.

### 317. Patchy Post-traumatic Atrophy of the Bones of the Knee.

G. M. F. SINDING-LARSEN (*Tidsskrift, d. Norske Lægeforening*, February 1st, 1925, p. 128) records the following case as a warning to surgeons who are apt to resect a knee-joint on the assumption that it is tuberculous, and without employing such diagnostic methods as the x rays and tuberculin tests. The patient was a steward, aged 40, whose sister had died of pulmonary tuberculosis; he had bad good health till June, 1922, when the inner side of the right knee was struck by a barrel. The knee at once became swollen and gradually stiffened. Tuberculosis being diagnosed, immobilization in plaster and treatment with sunlight were prescribed. When first seen by the author in May, 1923, he limped with a stick, the circumference of the right knee was 1 inch more than that of its fellow, the range of movement was 20 degrees, and the muscles of the thigh were atrophied. Clinically, the case seemed to be one of fibrotic fungoid inflammation. But the x rays showed a curious patchy atrophy of the femur, tibia, and patella, associated in some places with sclerotic changes surrounding the atrophic patches. The interpretations of the skiagrams by various authorities differed greatly, and the author was about to resect the joint on the assumption that it was tuberculous, and that this was the shortest way to recovery, when, as a precautionary measure, he decided to test with tuberculin. A Pirquet test and successive subcutaneous injections of tuberculin, up to a dose of 2.5 cc., proved completely negative. Chronic arthritis with patchy atrophy of the bone was now diagnosed, and treatment with diathermy, massage, and careful active movements was instituted. The patient recovered rapidly and was able to return to work in September, 1923. A year later he was again examined, and the knee was found to be normal. There was no

pain or limitation of movement, and skiagrams showed hardly a trace of patchy atrophy. The thigh muscles were again well developed, and he stated that during the past year he had been perfectly well. The author appends reproductions of the skiagrams and a report by Gösta Forssell thereon.

### 318. Mycetoma of the Foot in Europe.

F. PUTZU (*Arch. Ital. di Chir.*, November, 1924, p. 585), who records an illustrative case, states that mycetoma of the foot, which is very prevalent in the East Indies, where it is known as madura foot, as well as in the Malay States, the Philippines, and other districts in Africa and America, is uncommon in temperate climates. In Europe only ten cases have been recorded, almost all of which occurred in Italy. Putzu's case was in a boy, aged 16, a native of Cagliari in Sardinia, in whom the disease started at the age of 9, without any apparent cause, in the form of a small swelling on the sole of the size and shape of a kidney bean. Within the last two years its growth had been rapid and considerable as the result of an injury. The foot was much swollen and covered with numerous pustules from which there was a blood-stained discharge containing yellowish granules. Apart from a feeling of weight the condition did not cause the patient any inconvenience. The organism isolated was identical in its morphological, cultural, and experimental features with actinomyces. Putzu points out that this is the second case in Europe—the first having been reported by Tusini in 1900—and the first in Sardinia in which the diagnosis of mycetoma of the foot has been established by bacteriological examination. This case also shows that mycetoma of the foot is not always due to a single species of fungus—namely, *Monosporium apio-spermum*—as previous publications would suggest. Mycetoma of the foot as observed in temperate climates, like that seen in the tropics, has a varied etiology, although the cases closely resemble each other clinically and anatomically. In treatment of mycetoma of the foot all methods except operation are absolutely useless. Administration of large doses of iodine, either by mouth in the form of iodides or subcutaneously, sea-bathing, and heliotherapy, which are so valuable in tuberculous affections, did not have any effect in Putzu's cases. The same may be said of radiotherapy, which may be of some value in cervical actinomycosis. In Putzu's case a supramalleolar amputation was performed. The subsequent history of the case is not recorded.

### 319. Pseudo-cholelithiasis.

L. SCHAAP (*Nederl. Tijdschr. v. Geneesk.*, December 13th, 1924, p. 2991), who records two illustrative cases, refers to the condition simulating cholelithiasis first described by Keen in 1833, and since by Kerto and Riedel in Germany in 1902 and 1903, and by Taylor, Bond, Stuart, Nairne, Porter, and Ricketts in England and the United States, and by Terrillon, Longuet, and Semolaigne in France. Non-calculous cholecystitis appears to be more frequent than is generally supposed. While Henkel, from statistics at Göttingen, found only 7 examples in a series of 100 cases of chronic cholecystitis, the recent statistics of Smithies show that among 1,000 cases calculi could be excluded in no less than half. In most cases a clinical distinction is impossible. Examination with the duodenal tube may be of assistance in that the presence of stones may sometimes be recognized by the size of the cholesterol crystals in the duodenal fluid removed. Only a positive result, however, is of any value in such cases. The practical importance of this subject is that in treating patients who present the clinical picture of cholelithiasis the possibility of calculi being absent should be taken into consideration, so as to avoid a surprise on finding the gall bladder empty on laparotomy.

### 320. Intestinal Obstruction due to Inspissated Mucus.

J. EXALTO (*Deut. Zeit. f. Chir.*, December, 1924, p. 52), who records an illustrative case, points out that in intestinal obstruction in the newborn the possibility of inspissated plugs of mucus and epithelium should be considered as a factor as well as such causes as atresia, intussusception, volvulus, or strangulation by bands. There are three possible explanations of intestinal obstruction in the newborn by inspissated mucus—namely, (1) delay in secretion of bile, (2) defective secretion of bile, (3) some disturbance in the bile ducts or intestine, so that little or no bile enters the intestine. As a result there is a formation of firm plugs consisting of mucus, epithelial cells, and calcareous concretions, greyish-white in colour owing to the absence of bile. In some of these cases the plugs are situated in the rectum and are evacuated spontaneously or as the result of an enema. In other cases they become lodged higher up in the intestine and cause complete obstruction, which always ends fatally. Cases of this kind are extremely rare. Apparently the only cases reported in English literature are those by Ballou and Brennan (*Journ. Amer. Med. Assoc.*, 1919, lxxiii, p. 1832) and

Hughes (*Brit. Journ. Child. Dis.*, 1922, xix, p. 32). Exalto's case occurred in a female infant, aged 3 days, who was admitted to hospital because it had not passed any meconium, but had been constantly vomiting. The abdomen was tense. Passage of a sound 25 cm. up the anus was followed by the discharge of a white slimy mass 8 cm. long, but no meconium. A diagnosis of intestinal atresia was made, and laparotomy was performed without the nature of the stenosis being discovered. Death took place five days later. The autopsy showed that the ileum was obstructed by a number of plugs consisting of mucus, epithelial cells, and calcium carbonate.

## Therapeutics.

### 321. Carbon Tetrachloride as an Anthelmintic.

A. C. CHANDLER and A. K. MUKERJI (*Indian Med. Gazette*, February, 1925, p. 61) give notes on carbon tetrachloride as an anthelmintic considered from the points of view of safety, effectiveness, simplicity, cheapness, and lack of unpleasantness in administration. They conclude that a single dose of from 45 to 75 minims (for an adult) of chemically pure carbon tetrachloride is safer than any other anthelmintic, provided that a saline purge is administered, that the patient is well nourished, has a normal liver, abstains from alcohol before and after treatment, and receives a diet rich in carbohydrates and poor in fats. They are of opinion that one such treatment will cure from 70 to 90 per cent. of necator infections and about 30 to 40 per cent. of ancylostome infections. As to simplicity of administration, the fact that one dose is sufficient renders it superior for mass treatment. Although the after-effects may be slight giddiness and drowsiness, patients are unanimous in preferring it to chenopodium and thymol, and it has the further advantage of being much cheaper. As regards administration, a 70 minim dose in skimmed milk is recommended. Chandler and Mukerji add that carbon tetrachloride has a distinct ascaricidal action, but is more effective when combined with chenopodium. Given orally it had a more decided action on oxyurias than any other anthelmintic tried. Good results have followed its administration rectally in warm milk, and the authors consider this method, combined with a dose by mouth, worthy of further trial.

### 322. Diathermy in Gonococcal Infection.

E. P. CUMBERBATCH and C. A. ROBINSON (*Brit. Journ. Ven. Dis.*, vol. i, No. 1, January, 1925, p. 23), recognizing that the gonococcus can be destroyed by a temperature insufficient to harm living tissues, treated over 150 gonococcal infections by diathermy. By this means the temperature of the tissues can be raised *en masse*, the heat being generated in the tissues themselves and produced faster than it can be removed by convection. With currents oscillating a million or more times a second the tissues can be heated to 114°F. with only a sensation of heat resulting, but above this temperature pain is produced, and the authors consider it unsafe to increase the current to a strength at which pain is felt. Diathermy appears to act (1) directly by diminishing the vitality of the gonococci and destroying them in certain situations where a high temperature can be safely attained, and (2) indirectly by increasing the power of the tissues to remove infecting organisms. In the treatment of infections in women the authors applied diathermy first to the urethra and then to the cervix uteri by means of bougie electrodes, the current being gradually increased until the sensation of heat gave place to pain; the current was then reduced until the pain disappeared, and was maintained at that strength for ten minutes. This method of treatment was present or not. The treatment was repeated twice weekly for from three to five sessions. Cumberbatch and Robinson remark that in cases where a vaginal speculum cannot be introduced the current can be applied for twenty minutes through an electrode in the rectum. In children high temperatures were not attempted, but the exposure was prolonged. The authors claim that gonococcal infection in both sexes can be cured or arrested by the application of diathermy to the primary foci of infection.

### 323. Intraspinal Injections of Gentian Violet.

B. I. GOLDBERG (*Boston Med. and Surg. Journ.*, February 19th, 1925, p. 359) discusses the value of frequent drainage and intraspinal injections of gentian violet in meningial infections with Gram-positive organisms. Notes of two cases of meningitis are recorded in which intraspinal injections of gentian violet, diluted 1 in 250,000, were given two or three times a day, preceded by removal of from 50 to 60 c.cm. of cerebrospinal fluid. Although the cerebrospinal fluid in both cases

was purulent, no growth was obtainable on culture. One of the cases ended fatally, but in the other which had shown a typical temperature swinging daily from 99° to 104° for five and a half weeks there was a dramatic fall to the normal with complete recovery. Goldberg is uncertain to what extent this was due to the injection, since the removal of cerebro-spinal fluid before each injection may have contributed to the cure. The author's object is to call attention to the innocuousness of such intraspinal injections and their possible value in an otherwise hopeless condition.

## Laryngology and Otolaryngology.

### 324. Laryngeal Tuberculosis.

E. CURECHOD of Lausanne (*Arch. Intern. de Laryngol., d'Otol. et de Rhinol.*, November, 1924, p. 1028) describes the case of a woman, aged 40, who was a worker in wool; after six years in this occupation she developed a hard dry cough. On examination there was found pronounced deflection of the nasal septum with consequent mouth-breathing. The larynx showed a swelling of the anterior two-thirds of the left ventricular band, which reached almost to the middle line and hid the corresponding part of the vocal cord; there was also a thickening in the interarytenoid space. A section of the swelling was found to be strongly indicative of tuberculous disease. The condition cleared up under rest, galvanocautery treatment, and the application of lactic acid with some x-ray therapy. Curechod points out that the dust in a wool factory is considerable, and the condition of mouth-breathing tends to an irritation of the larynx and thus to a predisposition to tuberculous disease. He has ascertained that both the morbidity and the mortality from pulmonary diseases is greater in workers in dusty occupations than in other types of labour. This is notably the case with woollen workers, and is equally true in the case of phthisis and in other pulmonary diseases. Similar precise figures are not available in the case of laryngeal tuberculosis, and such data as are available are complicated by reference to the alcohol, tobacco, and other habits of the patients. Figures collected by Lamb, however, indicate that the proportion of pulmonary to laryngeal tuberculosis varies according to the type of dust in which the patient works. In the case of metallic dust the number of cases of laryngeal disease outnumber the pulmonary by 50 per cent. In the case of vegetable and mineral dust the cases of pulmonary phthisis outnumber those of laryngeal disease by about 30 per cent. The mode of inoculation of the laryngeal mucosa by the tubercle bacillus is still under discussion. It is suggested that the bacillus is carried by the particles of dust, of which wool would be a very ready carrier, and implanted on the laryngeal mucosa. This appears to be a possibility, and it has been confirmed by animal experiment; but the objection to it is that tubercles are often found in the deeper tissues without any trace of superficial change. It has been suggested that the infection is lymphatic, through the glands of the neck, a primary lesion existing in the lungs, or in the throat—especially the tonsils; this has not been proved by experiment. A suggestion that the infection is by the blood stream is not favoured by Curechod; he states that it is not confirmed by experiment on animals. He suggests that, though all these theories have very weak points, it is possible that the various routes may be concerned at different times and under different conditions.

325. J. SAFRANEK (*Med. Klin.*, February 1st, 1925, p. 157) reviews the pathology and treatment of laryngeal tuberculosis and records his own experience. It is, he finds, very rarely the first and only manifestation of tuberculosis: usually it results from infection by sputum in pulmonary disease. One-third of the cases of pulmonary tuberculosis present laryngeal symptoms. Climatic and local treatment should be combined with rest for the larynx obtained by "silence" treatment, in which even whispering is forbidden. In favourable cases of laryngeal tuberculosis the production of artificial pneumothorax is recommended. Local applications to the larynx are, he thinks, of little value, though a 10 to 20 per cent. menthol solution is much used. When local anaesthetics fail to relieve dysphagia the injection of alcohol into the superior laryngeal nerve, and in extreme cases section of this nerve, has been reported to be beneficial. Sfraneck considers that in every case of laryngeal tuberculosis, when the general and pulmonary conditions are favourable surgical removal of infected tissue from the larynx should be undertaken. He prefers galvanocautery and diathermy, but attaches great importance to tracheotomy: in numerous cases he has seen subsidence of laryngeal changes, as well as cessation of symptoms of stenosis, after tracheotomy. He therefore recommends tracheotomy in every case of laryngeal tuberculosis with commencing stenosis, and urges that this opera-

tion should not be delayed until symptoms of stenosis become severe. The great value of complete rest has led to the recent treatment of laryngeal tuberculosis by paralyzing the recurrent laryngeal nerve, either by surgical division or by the injection of alcohol. Sfraneck thinks that total extirpation of the larynx is only indicated in extremely rare cases, when the general and pulmonary conditions are favourable, and the tuberculosis has become diffused, extending to the cartilaginous wall of the larynx. He adds that, excluding very severe cases, laryngeal tuberculosis can be favourably influenced by suitable treatment, and in many cases definitely cured; pessimistic views as to cure should no longer be held.

### 326. Auditory Re-education in Middle-ear Catarrh.

J. RATEAU (*Rev. de Laryngol., d'Otol. et de Rhinol.*, December 31st, 1924, p. 806) describes the dry fibro-adhesive catarrh which follows catarrh with exudation. This condition commonly arises as a sequela of acute attacks of influenza, and also following disease of the accessory sinuses of the nose and of the nasal mucosa. It is more common in the city worker with a sedentary indoor occupation than in the outdoor worker of the country, and is often associated with alcoholism. An existing arterio-sclerosis or a chronic arthritis seems to predispose to middle-ear catarrh. The author describes at length the case of a professor who developed this condition after a very acute and severe attack of influenza. Tests showed middle-ear deafness with an ankylosed stapes, and indicated certain areas on the scale of sounds where hearing was still comparatively acute; the conversational voice was only heard very close to the ears. Treatment consisted in regular disinfection of the nasopharynx, digital massage of the muscles of the ear, electro-vibratory massage of the concha, and pneumatic massage of the tympanic membrane. Re-education to sound is effected by conveying to the patient musical notes from a mouth-organ which are conducted to the ear by means of Tiltot's tube. For the higher notes a flute is used and for the lower a piano, against which the patient is instructed to press his head; transconductors as well as aerial conduction is thus employed. Sessions of this treatment are given twice daily, and exercises with the voice through Tiltot's tube are added after a short time. In the case described by the author the hearing of conversational voice was increased in the two ears from 20 and 10 cm. to 50 and 20 cm. respectively, with a corresponding increase in the comfort of the patient. The progress of the patient is very carefully watched throughout, and tested by the Rinne and Swabach tests before and after inflation of the tympanum. If the time of these tests diminishes, and the difference between the hearing before and after inflation also diminishes, the condition of the ear is deteriorating, but so long as these periods are increasing progress is being made. By means of this procedure the interest of the patient is maintained, and the diminution of perception which follows diminution of transmission is prevented or retarded. Failing this the patient is prone to retire into himself, ceasing to make any attempt to take part in the conversation and doings of others.

## Obstetrics and Gynaecology.

### 327. Caesarean Operations in Two Stages.

R. VAUDESAL (*Bull. Soc. d'Obstét. et de Gynéc. de Paris*, 1924, 10, p. 787) records another successful instance of Portes's operation of Caesarean section followed by temporary exteriorization of the uterus. The patient had been in labour eighty hours and showed general contraction of the pelvis. The suture of the abdominal wall in preparation for hysterectomy was done in one layer, with bronze wire. The uterus was returned to the abdomen thirty-eight days later. The following contraindications for Portes's operation are tabulated: (1) death of the foetus—here embryotomy is preferable; (2) pelvic contraction permitting symphysiotomy or pubiotomy; (3) dystocia from pelvic tumour, unless the tumour can be removed at the same operation; (4) urgent maternal indications for rapid delivery—here vaginal Caesarean section will usually be preferable. J.-L. FAURE (*ibid.*, p. 792) believes that after abdominal Caesarean section in infected cases the insertion for about ten days of a Mikulicz drain (extending along the anterior surface of the uterus) will render exteriorization of the uterus unnecessary. P. GUÉNIOT (*ibid.*, p. 790), in support of this suggestion, recalls that Zarate in Buenos Aires had used a similar device, leaving a gauze drain of smaller size along the uterine wound for forty-eight hours: his four patients were discharged from hospital in about three weeks. Guéniot holds nevertheless that Portes's operation has a definite therapeutic place: it has the advantage of permitting continuous observation of the uterine scar and its secondary suture if necessary, so that in a later pregnancy there may be no risk of its rupture.

## 328. Pyelitis in Pregnancy.

G. TRIOLO (*Riv. d'Ostet. e Ginecol. Prat.*, December, 1924, p. 615) accepts the view that the pyelitis of pregnancy is very often due to a *B. coli* infection ascending from the bladder. Most commonly commencing in the sixth month, the onset of symptoms may be slow or acute. In the former case, typhoid or paratyphoid fever, malaria, or other pyrexial diseases may be suspected; in the latter, especially if the ureter be tender near McBurney's point, acute appendicitis may be simulated. Usually, however, urinary symptoms are present, and in any case the diagnosis is established by examination of the urine. Macroscopically there is usually nothing more than slight diffuse cloudiness to be noted; the reaction is acid. Microscopically numerous leucocytes, *B. coli*, and epithelial cells from the renal pelvis or bladder are to be found. Cystoscopy and ureteral catheterization are diagnostic methods which are not generally required. The prognosis is good, although recurrences in subsequent pregnancies are not uncommon. Treatment consists in rest, and the abundant ingestion of alkaline mineral waters, or water to which sodium bicarbonate has been added. In cases resisting this treatment resical lavage with silver nitrate (1/2 per cent.) or protargol (2 to 10 per cent.) is recommended, and may be combined with vaccine treatment. Exceptionally ureteral catheterization or lavage of the pelvis with silver preparations may be required. Triolo thinks that the artificial termination of pregnancy is very rarely necessary, and that it is of doubtful therapeutic utility.

## 329. Treatment of Abortion.

J. DE TORRE BLANCO (*Arch. de med., cir. y esp.*, December 27th, 1924, p. 633) in the treatment of non-infected abortion deprecates the method recommended by Polak and Becerro de Bengoa, which consists in the introduction of a slip of sterile gauze into the cervix, plugging the vagina, and administration of large doses of ergot, on the ground that introduction of the gauze may reactivate pre-existing inflammation of the adnexa, while plugging of the vagina may facilitate the development of infection. Of 159 cases of non-years in hospital and private practice, which were treated by curetting, in 137 there was not the slightest complication, while the rest had only a slight rise of temperature of two or three days' duration. In the case of infected incomplete abortion active intervention shortened the course of the disease. Blanco thinks that the best time to empty the uterus is at the onset of infection, before the disease has spread beyond the uterus. Evacuation of the uterus should be instrumental, not digital, as the digital method can never be complete. If the cervix is not dilated and is not competent, a hysterotomy should be performed, as is not infrequently the case. The cervix favours the development of a postabortal infection. After the uterus has been emptied it should be painted with iodine. In most cases no plugging is necessary apart from haemorrhage.

## Pathology.

## 330. The Value of Anatoxins.

G. RAMON (*Ann. de l'Inst. Pasteur*, January, 1925, p. 1) records a number of experiments which have been made to estimate the value of anatoxins, most of the work being performed on diphtheritic anatoxin. We referred to his previous work on anatoxin in our issue of March 22nd, 1924 (*Epitome*, para. 247). He has now found that a single subcutaneous injection of 25 c.c.m. into horses stimulated the production of antitoxin to such an extent that after ten days the serum contained 100 units, sometimes 200, and exceptionally even 300 units per cubic centimetre. For the preparation of diphtheritic anatoxin his usual method is to give a total of 1,030 c.c.m. of anatoxin spaced over nine injections made twice weekly; the horse is bled thirty-five days after the commencement. A more rapid method is to give 1,075 c.c.m. spaced over six injections, so that the first bleeding can be performed twenty-five days after the commencement. From fifty horses injected with the same batch of anatoxin the average yield of antitoxin was 525 units per cubic centimetre; this is better than in the old method, where only 400 units were obtained. He considers, therefore, that the method of immunization by the use of anatoxin has considerable advantages over the former method, in which crude toxin was employed; not only does it result in a better antitoxin, but it is much more rapid, and it entails no risks for the animals. He finds that the immunizing power of the anatoxin depends not so much on the dosage in which it is given as on the quality of the anatoxin. The higher the flocculating power the higher

is the immunizing power. By a series of tests he has found that there is a close correlation between these two powers; so much so that he proposes to introduce a new term for the measurement of the antigenic power of the anatoxin. This antigenic power he estimates as the number of units of antitoxin which are required to cause flocculation in 1 c.c.m. of anatoxin. An anatoxin, therefore, which is flocculated by 10 units of antitoxin is said to have a value of 10 anatoxic units. This unit is a relative one, as the immunizing power of a given anatoxin of course depends to a certain extent on the individual reaction of the animal employed. He finds that whereas crude diphtheritic toxin is destroyed by a temperature of 65° to 70° C. for one hour anatoxin is not so destroyed; not till a temperature of 72° C. is reached does the anatoxin become attenuated. It is therefore possible to sterilize it by Tyndall's method of repeated heating at low temperatures. Besides diphtheritic anatoxin other toxins have now been modified by formal and heat with the production of anatoxins; in practice these have proved of great value. They comprise tetanus, botulinus, and gas gangrene anatoxins. Lastly, he has found that certain other poisons, such as abrin and the venins, can be so modified, and that the anatoxins so obtained are able to give rise, on injection into animals, to the formation of antitoxins.

## 331. Symbolism of Diphtheria Bacilli.

AEIRA ADACHI (*Ichij. Journ. Exper. Med.*, December 20th, 1924, p. 1) states that, in spite of numerous investigations into the structure and life-history of the diphtheria bacillus, our knowledge is still very incomplete; many questions require further investigation, and in particular the type of diphtheria bacillus in a given case, and whether present in pure culture or mixed with pathogenic or saprophytic bacteria. The determination of the relative virulence of a given infection or culture by animal experiment has received considerable attention during recent years, but much remains to be done. Nicolai instituted extensive researches, adding other bacteria to cultures of *B. diphtheriae* with a view to determining whether the latter organisms grow more or less luxuriantly when so mixed, and whether any alteration was produced in their virulence, as determined by experiments on animals. Adachi describes various similar researches carried out during the last few years, and thinks that it is possible to draw the following conclusions: (1) The production of acid and spores by diphtheria bacilli was not affected by the presence of *li*, Friedländer's bacillus, nor observation did not disclose any increased virulence of *B. diphtheriae* in mixed culture. (2) Bacteriological diagnosis of diphtheria was rendered more difficult by the presence of staphylococci and of Friedländer's bacillus, but when streptococci or *O. albicans* were present they did not interfere. (3) The "suppression treatment" of diphtheria carriers by *B. coli* and *B. acid lactici* has been objected to on biological grounds, as the antagonistic influence of these bacilli on *B. diphtheriae* has not been definitely proved. It seemed more probable that spraying with cultures of staphylococci and pneumobacilli would be successful in the treatment of "carriers."

## 332. Local Effects of Intramuscular Injections.

H. W. ACTON and R. N. CHOPRA (*Indian Journ. Med. Res.*, October, 1924, p. 251), as the result of experiments on rabbits with intragastric injections of 20 mg. of sodium and potassium tartar emetic, 16 mg. of eucetino hydrochloride, and 80 mg. of quinine dihydrochloride, have come to the following conclusions: (1) Antimony, emetine, and quinine, when injected intramuscularly for the treatment of kala-azar, amoebiasis, and malaria respectively, all produce local effects upon the tissues. (2) Antimony causes oedema, irritation, and pain, emetine produces local haemorrhages and bruising, and quinine oedema and necrosis. (3) Quinine dihydrochloride exerts its effects on the tissues in two ways: (a) the liberation of the acid radicle causes oedema, irritation, and pain; (b) the base, acting as a protoplasmic poison, causes death of the surrounding tissues. (4) The salts of the four main alkaloids of cinchona bark all cause oedema, irritation, and necrosis of the tissues. (5) Cinchonine hydrochloride, when injected into the tissues, produces necrosis and oedema, and is the weakest alkaloid therapeutically. (6) The injection of these alkaloidal salts into the muscles of man should never be undertaken, since human muscle tissue is unable to live in the presence of these bases at a high concentration—namely, 1 in 2,000—and there is also a slight danger of tetanus, due to introduction of tetanus spores owing to imperfect sterilization, the necrosed area forming a suitable nidus. (7) There is only one method of administering cinchona alkaloids, and that is by the mouth. Very immediate action is required, quinine bases should be injected intravenously.

#### 

G. MACCIOTTA (*Il Policlinico*, Sez. Prat., January 16th, 1925, p. 116) states that while almost all textbooks are agreed as to the possibility of relapses and second attacks of measles, such an occurrence is regarded as exceptional. Macciotta, however, records eight cases of relapse and three of second attacks, all of which were observed in the same epidemic during the spring of 1924, and occurred in about 1 per cent. of all cases of measles. Relapses appeared in children aged from 1 to 7 years within a few weeks of the primary attack, while the second attacks were in persons aged from 15 to 27 who had suffered from measles in infancy. Macciotta attributes the occurrence of relapses and second attacks to an exaltation of the virulence of the causal organism of measles on the one hand, and a diminution of organic resistance on the other. The two predominant factors in his cases were the familial and the tuberculous. Four of the patients were two pairs of brothers, and two were cousins. Five of the relapse cases were tuberculous, and tuberculous could not be excluded in the remainder. Of the three patients with second attacks, one subsequently died of pre-existing tuberculous and another showed signs of phthisis.

#### 

S. TRENTINI (*Rif. Med.*, January 12th, 1925, p. 24), who records an illustrative case of paratyphoid B infection in a woman, aged 26, together with the autopsy findings, states that while in some cases the clinical picture and pathological changes, on both naked-eye and microscopical examination, are the same in paratyphoid B infection as in typhoid, yet in other cases a distinction can be made. Several writers have described the following anatomical changes as characterizing paratyphoid infection: (1) The diphtheritic character of the intestinal lesions. (2) The ulcers are few in number and are only rarely found in connexion with Peyer's patches or the solitary follicles. (3) The ulcers are found in the upper part of the intestinal canal as well as in the colon down to the rectum. Some writers, such as Burchhardt and Huchschmann, regard ulcers in the colon as typical of paratyphoid infection. (4) There is generally no change in the lymphatic system of the intestine, mesenteric glands, and spleen, which in typhoid show the typical enlargement. Trentini's case, like 42 of the 75 cases of paratyphoid diagnosed bacteriologically by Sternberg, showed changes identical with those of typhoid. This confirms the conclusion recently reached by Suzuki, who, after studying 69 cases of paratyphoid fever, was convinced that in this condition intestinal lesions predominated in the form of follicular enteritis, but cases of paratyphoid were not infrequently found in which the lesions of the intestine, spleen, and lymphatic glands corresponded exactly with those of typhoid fever.

#### 

R. MELCHIOR (*Paris Méd.*, January 10th, 1925, p. 47), who records two illustrative cases, states that three groups of post-typhoid osteo-periostitis can be distinguished bacteriologically. The first group consists of cases due either to *B. typhosus* only or *B. paratyphosus* B only; the second group consists of cases due to staphylococci only; while in the third group staphylococci are associated with typhoid bacilli. Melchior thinks that vaccine therapy is indicated in the last two groups, and may be of service in the first group when the course is chronic. The group to which the case belongs is determined by bacteriological examination, if possible, while in other cases clinical methods will decide. The author adds that a post-typhoid complication, which is not relieved by rest and is associated with the persistence of general symptoms, is not due to the typhoid bacillus, which is only slightly virulent and is easily rendered harmless by the antibodies accumulated in the organism.

#### 

LOUSTE, CAILLIAU, and DARQUIER (*Bull. Soc. Française de Derm. et de Syph.*, January, 1925, p. 10) refer to their case of hypertrophic tuberculosis of the face simulating Oriental sore (see BRITISH MEDICAL JOURNAL, March 7th, 1925, *Epitome*, para. 248), and now record another unusual case of tuberculosis in a man aged 25. At the beginning of October, 1924, he noticed a small erosion, the size of a lentil, on the left side of the labio-preputial groove, slightly painful, with marked

preputial oedema. The ulcer was treated with silver nitrate and fomentations were applied. A month later a mass of inflamed glands in the left groin rendered walking painful. At the beginning of December there was a nodule as large as a pea at the site of the original ulcer, slightly mobile, and almost painless on pressure. On its apex there was a small sinus from which a little yellowish purulent fluid exuded. The induration was limited and all oedema had disappeared. The mass of inflamed lymph glands in the left groin was as large as an egg, hard, painful on pressure, and adherent to the superficial and deep fascia. Both the Wassermann and Hecht reactions were negative. The diagnosis was a suppurating cyst of a preputial gland. The nodule was excised twelve days after admission; the operation wound healed in six days. On January 4th the inguinal bubo opened and discharged a small quantity of whitish pus which did not contain tubercle bacilli. Sections of tissue removed at the operation showed dense infiltration with giant cells, mononuclears, and plasma cells. Some sections contained acid-fast bacilli, which did not, however, stain well. Louste observes that the sections showed a typical picture of a tuberculous nodule. Radioscopy of the lungs gave no evidence of tuberculosis.

#### 

E. S. McDOWELL (*New York State Journ. of Med.*, January, 1925, p. 19), who records an illustrative case, remarks that many outbreaks of infectious jaundice have been reported in widely separated parts of New York State, but the cases have been mild, the onset of the disease insidious, and the organisms had disappeared by the time the nature of the disease was suspected. McDowell's case was in a man, aged 43, who had been working and sleeping in a kitchen infested with rats, but with no history of a rat bite. He suddenly became ill, with a temperature of 103°, and severe pains in the joints, back, and abdomen. Three days later he had complete anuria, became deeply jaundiced with haematemesis and melæna, and died about one week after the onset. The Wassermann reaction was negative. *Post mortem* the kidneys were large and swollen, and there were petechial haemorrhages throughout the gastro-intestinal tract. Microscopical examination showed acute glomerulo-nephritis, extensive destruction of the liver cells, and spirochaetes in the liver and kidneys. Inoculation of the blood of one of the rats on the premises into a guinea-pig produced all the symptoms of Weil's disease. Spirochaetes were obtained from the blood stream of the animal, reinjected into another guinea-pig, and the disease reproduced.

#### 

F. STARLINGER (*Deut. Zeit. f. Chir.*, January, 1925, p. 408), who records a case in a man, aged 37, the father of a healthy child, in whom the growth had been present for eighteen years, states that the first example of a tumour of the vas deferens was reported in 1819 by Cloquet, the growth in his case being a lipoma. Since then 118 authentic cases have been recorded. In about 50 per cent. there was a history of trauma. The majority were lipomas, which were often of peritoneal origin, and sometimes showed a diffuse infiltrating growth, frequently relapsed, and occasionally formed metastases. The growths in this region in order of frequency are lipomas, dermoids, mixed tumours, fibromas, lymphangiomas, myomas, myxomas, and carcinomas. Starlinger's case is the third on record of a benign tumour of the vas deferens with a mainly myxomatous composition. The typical feature of a benign tumour of the vas deferens is its long duration, the growth dating back to puberty without there being any causal connexion with that epoch, and it is not until after the lapse of many years that the patients seek medical advice owing to increase in size of the tumour. Actual neuralgia in the vas deferens is not complained of, but only dragging pains of varying intensity. Clinical differentiation from the much more frequent condition of hydrocele is often impossible without exploratory puncture, especially as myxomatous tumours are translucent, a feature formerly supposed to be peculiar to hydrocele. The more frequent situation of the tumours on the left side is probably of no significance in view of the small number of cases observed.

## 339. Treatment of Burns.

1. S. RAYDIN and L. K. FERGUSON (*Ann. Surg.*, February, 1925, p. 439) remark that the mortality of severely burned patients is so high that it is equalled by but few conditions which the surgeon has to treat. They adopted the following lines of treatment in a series of cases, with satisfactory results. After admission the patient was placed in bed with an electric cabinet over him containing lamps to keep a temperature of 100° F. The burned area was covered with gauze soaked in 1/2 per cent. novocain solution to which had been added 1 in 1,000 adrenaline in the proportion of 10 minims to each fluid ounce of novocain; this anesthetized the burned area and allowed the removal of the burned skin and also the opening of the blebs. Fluid was given by mouth or intravenously. On removal of the gauze the area was sprayed three-hourly with a freshly prepared 2 per cent. solution of dichloramin T. If toxemia developed the removal of blood followed by transfusion was attended with considerable success. Skin grafts were applied later. The urine was examined in all cases and showed no evidence of nephritis. In fifteen recorded cases only one death occurred, and this was due to gastro-enteritis, probably secondary to the burn. The authors discuss in some detail the occurrence and treatment of toxæmia and acidosis.

340. A. M. WILLIS (*Journ. Amer. Med. Assoc.*, February 28th, 1925, p. 655) reports several cases of the treatment of burns by the surgical removal of the destroyed tissues, thus preventing or diminishing the occurrence of secondary traumatic shock. The points emphasized are the relief from pain that is thus obtained, the rapid subsidence of pyrexia, slowing of the pulse rate, and acceleration of the healing process. As the result of experimental investigation it was found that in burns, as in traumatic shock, there occurred an increased concentration of the blood corpuscle count and blood nitrogen, while the alkali reserve was not much affected until later; with these changes there was a gradual fall in the blood pressure. When, however, excision of the burnt areas was practised the blood changes were absent or very slight, and no evidence of structural damage was detected in those organs which, in the absence of this treatment, showed such changes.

## 341. Duodenal Dilatation caused by Omental Adhesions.

M. BAUMGARTNER (*Bull. et Mém. Soc. Nat. de Chir.*, January 24th, 1925, p. 35) discusses an interesting case reported by G. Pilven of a woman who suffered from severe abdominal pain and vomiting commencing two or three hours after every meal. General examination revealed nothing abnormal, but the radiologist reported that the food collected in the second and third parts of the duodenum. When this occurred the patient complained of pain. At the operation the stomach and duodenum were found to be normal except for marked dilatation of the duodenum. This was due to the omentum being firmly bound down by old adhesions, probably tuberculous, producing partial occlusion of the termination of the duodenum. The adhesions were divided and the compression was thereby relieved. In the absence of any other organic lesion the transverse colon and the hepatic flexure were fixed to the parietal peritoneum to prevent any further trouble. The patient was completely relieved, and a subsequent radiographic examination demonstrated that the dilatation of the duodenum had disappeared.

## 342. Sarcoma Statistics.

H. SCHOENECKE (*Deut. Zeit. f. Chir.*, January, 1925, p. 420) gives the following statistics of 102 cases of sarcoma which had been treated at the first surgical department of the Hamburg University Clinic in the General Hospital at Eppendorf from 1901 to 1921: 72 were sarcomas of bone, and in the remaining 30 glands or muscles were mainly affected. The following bones were affected in order of frequency: femur (20), pelvis (15), superior maxilla (10), leg (8), upper arm (5), scapula, knee, foot, forearm (3 cases each), clavicle and inferior maxilla (1 case each). In 17, or 23.6 per cent. of the 72 cases, there was a history of trauma. Of the 102 cases, 73, or 71.57 per cent., were males and 29, or 28.43 per cent., females. The average age was 36.6 years. Surgical operations were performed in the case of 57 patients, 14 received irradiation treatment, and 7 were curetted and had irradiation as well. Among 32 in whom a radical operation or resection was performed there were 5 deaths, a mortality of 15.6 per cent. The mortality among those curetted was 24 per cent., and among those treated by irradiation 35.6 per cent. Of the 7 treated by curetting and irradiation 1 died. The total mortality during the stay in hospital was 33.1 per cent.

654 B

## Therapeutics.

## 343. Theocine Treatment of Hypertension.

F. CASTELLOTTI (*Cuore e circolazione*, January, 1925, p. 22) studied the action of theocine, which is also known as theophylline or dimethyl-xanthine, with the Riva-Rocci sphygmomanometer in 11 cases of arterial hypertension, 3 of which were of cardio-renal origin, and 1 case of angina pectoris. Pure theocine was given, because there are some differences of opinion as to the value of theocine sodium acetate. The drug was given in fractional doses, starting with 20 cg. the first day and gradually increasing the dose according to the more or less pronounced fall of blood pressure obtained. No other drugs were given at the same time. The blood pressure was taken at 10 a.m., as long as possible after sleep, and at 5 p.m., as long as possible after food. Castellotti's conclusions are as follows: (1) Theocine is an excellent hypotensive drug, but should be used with caution. Each dose should consist of 20 cg., and the total amount daily be ranged from 60 to 80 cg. (2) The drug may be well tolerated even in small doses; it is therefore advisable to proceed to its prolonged administration by minute doses for three or four days. (3) The fall of blood pressure may be considerable—namely, 30–40 mm. Hg for the diastolic and 100 mm. Hg for the systolic pressure. (4) The diastolic pressure usually shows a more marked and persistent fall than the systolic. (5) Theocine causes an abundant initial diuresis at the same time as the fall of blood pressure, but while the latter gradually becomes less marked the diuresis tends to remain constant.

## 344. Mandragora in Whooping-cough.

H. DECLERCQ (*Bull. Soc. de Théor.*, January 14th, 1925, p. 18) remarks that, though in the Middle Ages mandragora was an important narcotic, it has long been absent from the *Pharmacopœia*. The only medical practitioners who have been in favour of restoring it were Alchea in 1854, and Benjamin Ward Richardson in 1888. The latter obtained from a decoction of mandragora root effects similar to those produced by chloral, and characterized by symptoms of local and general anaesthesia. Mandragora has recently been the object of chemical research, which appears to confirm the ancient view of its pharmacodynamical effects. Ahrens, in 1890, isolated from the root an alkaloid with mydriatic properties and isomeric with atropine, hyoscyamine, and hyoscyne; he named this mandragorine. A few years later Thoms showed that mandragorine was chiefly composed of hyoscyamine and scopolamine. Hesse extracted from the root a mixture of alkaloids in which hyoscyamine predominated, and hyoscyne, pseudo-hyoscyamine, and mandragorine were also found. The presence of these principles explained the inhibitory action of mandragora on the nerve centres, and its power to abolish the reflexes more or less completely. According to Declercq, the principal indications for mandragora are the pain of gastric ulcer, spasms associated with enterocolitis, tenesmus caused by anal fissure and piles, hepatic and renal colic, and dysmenorrhœa; but it is chiefly as a sedative of the cough in pertussis that it is found of the greatest value. A 5 per cent. tincture of mandragora root is given in doses of half a drop in children less than 1 year old, and in doses of 1 to 10 drops in older children, aged 2 to 8, every three hours. The paroxysms diminished in frequency and intensity, the whoops were reduced in number and often disappeared entirely, the vomiting became less frequent, and the bronchial secretion less profuse. In most of the children so treated the symptoms were decreased and the duration of the disease was distinctly shortened.

## 345. Bulbocapnine in Tremors.

A RESEARCH carried on in the Norvo Clinic of the University of Amsterdam, which is under the direction of Professor B. Brouwer at the Binnevestigingshuis, to determine the therapeutic action of bulbocapnine in diseases associated with tremors, forms the subject of a communication in English by H. DE JONG and G. SCHALTENBRAND (*Neurotherapie*, Nos. 1 and 2, January–April, 1925). This communication contains observations on eight new cases and on six cases already published at the end of 1924 in the *Klinische Wochenschrift und Neurotherapie*, vol. vi, 1924—namely, eleven cases of paralysis agitans, one of cerebellar tumour, one of tremor essentialis, and one of tromoparalysis tabiformis. The authors claim to have shown that neither the daily variations of tremors nor the results of treatment by suggestion were comparable with the effects of injecting bulbocapnine. Of seven cases of hyperkinesia two were uninfluenced by this drug: the amplitude of the tremors was often reduced almost to zero, while the frequency was never altered. On the other hand, in athetosis and in choreiform movements there was a clear reduction of the frequency of the movements, while the lessening of the amplitude was

less marked. Clonns and tremors were harder to arouse after administration of bulbocepinine; they disappeared more easily, were reduced in amplitude, and occasionally were entirely eliminated. The authors also compare the effects of bulbocepinine and scopalamine on seven cases of paralysis agitans. It was found that in general scopalamine acted more intensely than bulbocepinine, and its effect lasted longer. They add that bulbocepinine has probably the advantage of a constant effect, the absence of habit formation, and of the need of increasing dosage to produce an effect; no unfavourable symptoms followed the cessation of treatment. Scopalamine therapy long continued had all these drawbacks. From this they conclude that both drugs have a place in the treatment of tremor.

## Diseases of Children.

### 336. Rectal Prolapse in Children.

I. EKEHORN (*Acta Chir. Scand.*, January 21st, 1925, p. 397) reviews the results obtained in two Swedish hospitals with the operation which he devised in 1909 for the radical cure of prolapse of the rectum in children. The operation consists in anchoring the pelvic portion of the rectum to the lower portion of the sacrum by means of a ligature, passing through the posterior wall of the rectum, and penetrating its lumen. In 27 cases the age of the oldest patient was 9 years, and of the youngest 1 year. There were no deaths, and the operation was attended by so little discomfort that the patients were able to defecate at once in the normal manner. Investigations in July, 1924, of the ultimate results failed to disclose the whereabouts of 7; of the remaining 20, of whom 15 had been operated on more than five years earlier, it was found that without exception the prolapse was permanently cured, and there were no longer any symptoms. There were, indeed, 3 cases in which, immediately after discharge, there had been a slight recurrence of the prolapse, but this was only transitory. Discussing the possibility that the passing of a ligature through the whole thickness of the gut in two places might lead to a phlegmonous inflammation of the retrorectal tissues, the author finds that this mishap does not occur.

### 347. Milk Acidification in Infant Feeding.

THE buffer value of cow's milk is considerably above that of human milk, and it neutralizes a larger amount of the hydrochloric acid of the stomach. To counteract this excess of buffer salts, and thus bring the digestibility of cow's milk nearer that of human milk, BERNAN S. DUNHAM (*Amer. Journ. Dis. Child.*, February, 1925, p. 200) has used in infant feeding a mixture of 1 oz. of apple elder vinegar, of an acidity of 5 to 6 per cent. acetic acid, to 15 oz. cow's milk, or one teaspoonful of vinegar to 3 oz. milk. This ratio was used until about the tenth month of age, after which in healthy infants the vinegar milk was gradually replaced by sweet milk, and the vinegar was entirely omitted by the end of the first year. The amount of vinegar milk prescribed for each infant was about  $2\frac{1}{2}$  to  $2\frac{3}{4}$  oz. per pound of body weight for those weighing under 14 lb. The vinegar milk was given undiluted, except to infants younger than 2 months, who received 4 oz. water or gruel in the total daily feeding. Corn syrup previously diluted with an equal amount of water was added in the proportion of 1 oz. of the dilute syrup to 16 oz. of vinegar milk, the total daily addition seldom exceeding  $1\frac{1}{2}$  oz., and this was reduced after cereal feeds were commenced. Feeds were given at four-hour intervals. Spoon feeds of 3 oz. or more of 6 per cent. cereal gruel were given to healthy babies twice daily, before milk, after the third month, and half that quantity of vegetable mash once daily, also before milk, after the fifth month. Extra water was offered between meals. Orange juice and cod-liver oil were given as a routine as soon as the digestive condition permitted. Disturbance of the digestion was a rare occurrence and was corrected by a temporary reduction of the sugar and fat elements of the food. Dunham claims to have had good results in boarded-out babies, infantile atrophy, pylorospasm, syphilis, rickets, and parenteral infections.

### 348. Pneumonia in Newborn Infants.

W. C. JOHNSON and J. R. MEYER (*Amer. Journ. Obstet. and Gyn.*, February, 1925, p. 151) report that in a series of 500 autopsies on stillborn and newborn babies no fewer than 97, or 19.4 per cent., showed evidence of pneumonia. They agree with Browne (*BRITISH MEDICAL JOURNAL*, March 25th, 1922, p. 469) that diagnosis of pneumonia is difficult in the newborn subject, and in the absence of microscopic examination impossible at autopsy. The symptoms and signs are meagre and inconstant, and most cases are practically afebrile. After death the lungs may sink or float,

according to the degree of atelectasis present; they are fleshy rather than consolidated, and pleuritis is rare. Many of the lungs showed a uniformly diffused inflammatory process, which might affect equally all the alveoli of a lung. The intra-alveolar exudate contained a small number of polymorphs, a few mononuclear cells, and a variable number of erythrocytes, with little or no fibrin. According to the authors only about one-fifth of the deaths from pneumonia follow post-natal infections, and of these the great majority are in premature infants. Of the 97 deaths from pneumonia 68 were attributed to ante-natal or intra-partum infection brought about by aspiration of infected fluid from the amniotic sac; the evidence of such aspiration was the presence within the alveoli of cornified epidermal cells and fat from the vernix caseosa. Another sign pointing to infection of the amniotic sac as the cause of pneumonia was acute inflammation of the placenta and membranes which was present in the great majority of the cases examined. It is added that mothers with infection of the amniotic sac during dry labour show few septic manifestations, and that the danger appears to be disproportionately greater for the child. A frequent cause of post-natal infection leading to pneumonia in premature infants was aspiration of food.

### 349. Sarcoma of the Uterus in Childhood.

F. VIGI (*Bull. della sci. med.*, November-December, 1924, p. 750) records a case of uterine sarcoma in an infant aged 26 months, and has collected twenty others from the literature occurring in children aged from a few months to 17 years. The commonest form of sarcoma of the uterus in childhood is that affecting the cervix, in which the growth has almost always the appearance of a roundish irregular polypoid mass resembling the sarcoma of the cervix in the adult known by the name of Pfannenstiel's sarcoma. When the sarcoma attains a considerable size it often produces dilatation of the vagina and protrudes from the vulvar orifice in the form of a fleshy readily bleeding growth, especially when there is a rapid increase of abdominal pressure as in crying, micturition, etc. As a rule the first sign of the disease is vaginal haemorrhage. The loss of blood, which is sometimes scanty and occurs only at intervals, may suddenly become very severe and recur at brief intervals so as to cause profound anaemia. In some cases there is not merely a flow of blood but a thick or extremely fetid puriform discharge due to disintegration of the growth. Occasionally the discharge may cease and the temperature rise simultaneously. On vaginal examination there is a sudden escape of pus mingled with fragments of necrotic tissue, but this is rather the exception than the rule. Disturbance of micturition is a very common early symptom, and is due to invasion of the uterovesical space by the growth. Dilatation of the bladder rapidly ensues owing to prolonged and painful efforts to pass urine. Cystitis develops, and finally pyelonephritis. All observers are agreed that the rectum is hardly ever involved. In exceptional cases the sarcoma arises from the body of the uterus, either from the endometrium or less frequently from the connective tissue of the walls or fundus.

## Obstetrics and Gynaecology.

### 350. Interstitial Pregnancy.

J. C. LITZENBERG (*Amer. Journ. Obstet. and Gyn.*, January, 1925, p. 22) describes the microscopical examination by serial sections of a uterus removed for an interstitial pregnancy of not more than three weeks' duration; the operation was performed twelve days after a missed menstruation and before the onset of pain or internal haemorrhage. He found the uterine muscle hypertrophied, especially on the side of the pregnancy; true decidual formation had occurred within the uterus, but it was absent from the pregnant tube. Both tubes contained "decidua-like" cells in islets; these cells are regarded as being of trophoblastic origin. According to the author the structure of the tube and uterine wall favours early rupture of the tube and late rupture of the ovum capsule; the unusual haemorrhage following the latter is explained by the large size of the vessels, which may be eroded at the cornu of the uterus. W. E. LEVY (*ibid.*, p. 93) states that diagnosis of interstitial pregnancy is rarely made before rupture; it should be suspected, however, when the signs and symptoms of early pregnancy are supplemented by the usual symptoms of ectopic pregnancy. Pain usually occurs at an early stage, before death of the ovum has taken place. Objectively the sessile enlargement at one cornu of the uterus is somewhat characteristic. Owing to the likelihood of severe bleeding the prognosis is grave; reports from the literature give an average mortality of 1 in 7.

351. **Puerperal Infection treated by "914."**  
FAVREAU (*La Vie Médicale*, December 26th, 1924, p. 2059) describes the treatment of puerperal infection at the obstetrical clinic of the Bordeaux Faculty of Medicine. In every puerperal case in which there is a considerable rise of temperature a routine intravenous injection is given of 0.15 cg. of "914," repeated the following day if the temperature is still raised, and subsequently on alternate days. Local treatment consists in intravaginal injections of solutions of iodine or Dakin's solution. No bad effects were ever observed apart from symptoms of suffocation, such as shivering, cyanosis, and a feeling of slight shock, which were rapidly dispersed by intramuscular or subcutaneous injection of adrenaline. All the patients made a good recovery. The rationale of treatment by "914" is outlined as follows: (1) it has a powerful bactericidal action, whatever the organism may be; (2) it has a remarkable tonic action on the system; (3) the beneficial result may possibly be due to shock therapy. The treatment should not be employed when the kidneys are much affected.

febrils. The rabbit's cornea inoculated with the virus zoster is not immune to subsequent inoculation with the virus febrilis (Mariani). (6) Herpes febrilis does not confer immunity against varicella, whereas zoster confers immunity against varicella and is very probably identical with it etiologically. (7) The Bordet-Gengou reaction with antigen is negative with the serum of herpes febrilis (Netter), whereas the Bordet-Gengou reaction with antigen from zoster and varicella sera is positive with zoster and varicella sera (Netter).

### 355. The Blood Platelets in Goltre before and after Operation.

B. N. ROSENBAUM (*Zentralbl. f. Chir.*, November 22nd, 1924, p. 2580) examined the blood platelets in eight patients with goltre who were healthy apart from goltre at the time of operation. Whereas the normal blood-platelet count according to Fenton is 350,000-200,000, after operation the count in the eight cases ranged from 75,750 to 176,800. The following morphological changes were observed—namely, round, oval, long, caudate, small, moderate-sized, and large. Here and there giant forms were seen, characterized by a basophil protoplasm with granules in the centre. This polymorphism persisted after the operation. The thrombopenia was often accompanied by a premature onset of the menstrual flow, which was excessive in amount. The occurrence of menorrhagia after thyroidectomy, which had also been noted by Knäus, is explained as follows. Under normal conditions there is an equilibrium between the thyroid, spleen, ovary, and bone marrow, as is shown by a normal blood-platelet content of the blood. When this equilibrium is upset by damage to the spleen or thyroid, a deficiency of blood platelets occurs as well as menorrhagia.

### 356. Isolation of Typhoid and Paratyphoid Bacilli.

V. DE DOMINICIS (*Rif. med.*, December 8th, 1924, p. 1155) recommends the following rapid method for isolation of *B. typhosus*, *B. paratyphosus* A, *B. paratyphosus* B, and *B. coli* from the blood. About 20 c.c.m. of a medium consisting of 100 c.c.m. of bile, 1 g. of peptone, and 1 g. of stein is poured into each of three large test tubes. Sterilization is carried out for one hour at 100°C. for three consecutive days. In Koch's autoclave, and the tubes when needed are placed in a water-bath at 37°C. for three hours. The blood is drawn from the patient's elbow vein and distributed among the three test tubes, 2 c.c.m. being put in the first, 3 c.c.m. in the second, and 5 c.c.m. in the third. The inoculated tubes are then placed in the thermostat at 37°C., and at the end of twenty-four hours, if growth has occurred, the development of gas is studied as well as the motility of the organisms in a hanging drop and its staining properties. At the same time tubes of milk, lactose, gelatin, and agar are inoculated. To the culture medium 5 drops of antityphoid serum are then added, and at the end of two hours agglutination tests are employed. A similar method is adopted for the study of paratyphoid A and B bacilli and *B. coli*.

### 357. Elimination of Sulphuretted Hydrogen after Administration of Colloidal Sulphur.

C. MALOSSI (*Biochim. et exp. therap. speriment.*, December 31st, 1924, p. 513), as the result of tests on himself with his colleagues as controls, came to the following conclusions: (1) Colloidal sulphur given by mouth is eliminated in the proportion of one-tenth by the broncho-pulmonary system in the form of sulphuretted hydrogen. (2) The elimination by the respiratory tract is very rapid, beginning five minutes after administration of the colloidal sulphur and continuing for half an hour. (3) The elimination occurring during the first half-hour represents two-thirds of the total quantity excreted. (4) Sodium bicarbonate has a slight influence on the transformation of colloidal sulphur, inasmuch as it gives rise to a slight increase in dose of colloidal sulphur required to produce the reaction of sulphuretted hydrogen in the expired air. (5) The minimum dose of colloidal sulphur required to produce the reaction of sulphuretted hydrogen in the expired air is 5 cg., as compared with 80 cg. of precipitated sulphur; the time required by the same reaction is obtained, though in a much less degree, by precipitated sulphur. (6) The therapeutic conclusions to be drawn from these laboratory tests are two—namely, (i) a constant current of sulphuretted hydrogen through the respiratory tract should result from the repeated small doses of colloidal sulphur; (ii) this method should be employed in cases in which treatment by sulphuretted hydrogen has to be protracted, such as whooping-cough, bronchial asthma, and chronic disorders of the bronchial mucous membrane.

### 352. Hydatid Mole, Normal Pregnancy, and Chorion-epithelioma.

C. H. HERMANIDES (*Nederl. Tijdsch. v. Geneesk.*, January 10th, 1925, p. 152) remarks that the likelihood of chorion-epithelioma is much greater after a mole than after normal pregnancy, as is shown by the following statistics. According to van Dongen, in 1924, 40 per cent. of the cases of chorion-epithelioma are preceded by a mole, 25 per cent. by a normal confinement, 32 per cent. by abortion, and 3 per cent. by extrauterine pregnancy. Marchand, in 1895, reported that confinement was preceded in 46.4 per cent. by a mole, in 28.6 per cent. by normal confinement, in 21.4 per cent. by abortion, and in 3.6 per cent. by extrauterine pregnancy. Van der Hoeven estimates that chorion-epithelioma occurs once in every six thousand confinements, and a hydatid mole in every two or three thousand pregnancies. Usually some months elapse between the confinement and the development of chorion-epithelioma, but sometimes only fourteen to thirty days on the one hand, or as long as two or three years on the other, may intervene. Hermanides records a case in a woman, aged 35, the mother of five children, who, about a year after removal of a hydatid mole, gave birth to a living child, with a normal placenta; about five months later she developed the first signs of metastasis from chorion-epithelioma, the diagnosis of which was confirmed by the autopsy.

### A Case of Protracted Pregnancy.

C. J. ALOUS (*Nederl. Tijdsch. v. Geneesk.*, December 13th, 1924, p. 3011), who remarks (in confirmation of the generally accepted view) that pregnancies lasting more than 300 days are exceptional, records a case in which pregnancy lasted as long as 322 days. The patient was the mother of nine children, the last two of whom had been twins. Labour was normal, although the child was of unusually large size, its weight being over 12 lb. and its length 20 in.

## Pathology.

### 354. The Relation of Herpes Zoster to Herpes Febrilis.

B. LIPSCHÜTZ (*Wien. klin. Woch.*, January 15th, 1925, p. 89) summarizes the difference between the virus of herpes febrilis and that of zoster as follows: (1) The rabbit's cornea is remarkably susceptible to the virus of herpes febrilis, but only slightly so to that of herpes zoster. (2) Herpes febrilis is inoculable on the human skin after a short incubation period, and the lesion remains localized, while zoster is only inoculable on the skin of children within the first years of life after a long incubation period (nine to twelve days). In some cases after formation of the local lesion a generalized varicelliform eruption appears with typical nuclear inclusions. (3) Histologically herpes zoster is situated superficially in the skin, and healing takes place without scar formation, whereas the situation of herpes zoster is deeper, and later marked inflammation and suppuration occur, followed by coagulation, necrosis, and cicatrization. (4) Cytologically "herpes corpuscles" (Lipschütz) are abundant in the epithelium, but scanty in the corium in herpes febrilis, while in herpes zoster there is an abundance of "zoster corpuscles" in the epithelium, corium, and nuclei of the endothelium of the blood vessels. (5) Repeated attacks of herpes febrilis do not confer any immunity to herpes febrilis or zoster, but the rabbit's cornea inoculated with the virus of herpes febrilis acquires immunity to subsequent inoculation with herpes febrilis. On the other hand, an attack of herpes zoster confers immunity against zoster, but not against herpes

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 358. Herpes Zoster and Varicella.

LESNÉ and DE GENNES (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 19th, 1925, p. 221), opposing the view that herpes zoster and varicella have a common identity, draw attention to the following facts. Although varicella and herpes may be seen in the same person at short intervals or in the same family, the coexistence of varicella with measles or scarlet fever is still more common, but leads to no assertion that these diseases are identical. Many of the coincidences may be due to an abortive attack of varicella which has been overlooked and yet acts as a contagium. Varicella attacks infants, herpes very rarely; the varicella eruption is generalized, that of herpes is localized. Varicella never relapses; it confers a definite immunity against itself but not against herpes. The biological reactions are different; in varicella there is leukopenia with mononucleosis and the spinal fluid is normal, whereas, according to Sicard, there is a lymphocytic reaction in herpes. Herpes is not inoculable, varicella often is. On the other hand, many cases of varicella and herpes occurring in the same family have been recorded.

359. A. NETTER (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 26th, 1925, p. 249) refers to Kaudratitz's experiments (Vienna, 1922), in which four children who had not had chicken-pox were inoculated with the clear serum from herpetic vesicles. In three cases the inoculation was intradermal, in the other subcutaneous. Two of the former children developed, on the twelfth day, numerous transparent vesicles in the centre of red plaques (15 mm. in diameter) in the vicinity of the inoculation. These vesicles persisted for two or three days, then they dried. The fourth child four days after inoculation developed a local cellulitis which lasted for several days. All four children were then placed in a chicken-pox ward, sleeping and playing with the patients. The three successfully inoculated children did not contract varicella, while the fourth child (whose inoculation had failed) developed chicken-pox. Leiner reported that at the same time some children who had had herpes without having contracted varicella were also placed with the other patients in the chicken-pox ward and remained free. Netter attaches great importance to the investigation of complement deviation in the serum of herpes patients, in the presence of varicella antigen; the reaction was positive in 78 out of 80 cases. Lesné maintains, however, that the identity of varicella and of zona has not been proved; the plasma and cerebro-spinal fluid do not give identical reactions in the two diseases, and one disease does not confer immunity to the other. Huber has reported a case of two little girls who slept together. One developed varicella, and about a fortnight later her sister had a typical zona without any coexistent varicella vesicles; this child had not had varicella. Netter has collected several cases which appear to support his contention that herpes and varicella are identical.

360. SICARD and PARAF (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, March 5th, 1925, p. 301) state that the objections to considering varicella and herpes zoster identical are as follows: (1) Varicella confers immunity to varicella but not to zoster; varicella never relapses, whereas zoster may occur in persons who have had varicella. (2) Varicella can be produced in children by inoculation of the serum of varicella vesicles, whereas inoculation intradermally or subcutaneously of the fluid from zoster vesicles is not followed by a local or general reaction. (3) Spinal lymphocytosis, which Brissaud and Sicard found in zoster, does not occur in varicella. (4) Scarification of a rabbit's cornea with serum from a varicella vesicle produces keratitis, whereas inoculation with fluid from a zoster vesicle does not cause any corneal irritation. (5) In two cases recently observed by the authors inoculation of the serum of a zoster patient did not protect children exposed to varicella.

### 361. Primary Carcinoma of the Lungs.

B. M. FRIED (*Arch. Intern. Med.*, January 15th, 1925, p. 1) describes a series of ten cases of primary lung carcinoma, and maintains that the condition is much more frequent than is commonly believed. One characteristic of the disease is early metastasis, in the bones or brain very frequently, and the prominent symptoms may be caused by these metastases, so obscuring the primary lesion. Clinically, there are therefore two groups: typical—with the chief indications relating

to the chest organs; and atypical—with symptoms due to metastatic involvement. In typical cases the onset is usually gradual, a sharp, stabbing pain in the chest, due to early involvement of the pleura, being one of the most characteristic signs. The persistent absence of tubercle bacilli in the sputum, in the presence of persistent lung symptoms (cough, pain in the chest, and blood-streaked sputum), especially when there has been a gradually downward course of the case, should always suggest malignancy. Fried adds that the presence of tuberculosis does not necessarily exclude malignancy. McMahon, Carman, and Thomas and Farmer assert that a radiogram will enable a diagnosis to be made even in the early stages of the neoplasm.

### 362. The Sex Incidence of Rheumatic Diseases.

A. TANBERG (*Norsk Mag. f. Lægevidenskaben*, February, 1925, p. 139) quotes statistics from Norwegian sources to show that while the incidence of tonsillitis and rheumatic fever or acute rheumatism is the same for the two sexes, chronic rheumatic infections, apart from those of the muscles and nerves, are much more common in women than in men. Thus, in the ten-year period 1913-22 there were 6,453 cases of tonsillitis in men and 6,030 in women notified in Oslo. In the same period the notifications of rheumatic fever were 828 for men and 815 for women. But during a recent three-year period at the Sandefjord Hydro there was a marked preponderance of women over men among the patients suffering from chronic rheumatism, and 79 per cent. of the patients suffering from primary polyarthritis were women. The conclusion which the author feels justified in drawing is that, though acute rheumatism may be a microbial disease, chronic rheumatism is a condition largely influenced by the constitutional factor, the disease resembling in this respect Graves's disease and gout, which afflict the sexes most unequally. Though primary polyarthritis has been called "arthritis pauperum" because of the predilection it shows for the poorest classes in the community, the author is sceptical about the influence of such a factor as exposure to inclement atmospheric conditions, for the Norwegian fishermen and foresters seldom develop this disease, although they are much exposed to bad weather. On the other hand, the wives of such men often suffer from primary polyarthritis, though they spend most of their lives at home. As a further example of the influence of sex on the localization of rheumatic diseases, the author notes that approximately 60 per cent. of all patients suffering from sciatica are males.

## Surgery.

### 363. Acute Dilatation of the Stomach.

G. ROBERTSON (*Surg., Gyn. and Obstet.*, February, 1925, p. 206) points out that acute dilatations of the gastro-intestinal canal are affections of great interest to the surgeon, but that their etiology and pathology are somewhat obscure. The important features of the condition during life seen in a case recorded in detail were its rapid onset and swiftly fatal termination, the almost complete absence of vomiting until just before death, when it was severe, and the absence of any apparent exciting cause and of evidence of previous post-operative disturbances of the stomach. Three theories have been advanced to explain these conditions in the absence of any apparent cause. First, derangement of the nervous mechanism of the stomach causing a paralytic ileus; secondly, an altered secretory activity of the mucosa of the viscera involved; and, lastly, a mechanical ileus, the point of constriction being that where the superior mesenteric vessels cross the duodenum. In a second group of cases of this nature some definite lesion may be found after death, such as pneumonia or septic peritonitis, the latter condition leading to paresis of the whole intestinal canal. Next, there is the type in which dilatation follows some surgical operation. In such cases a general anaesthetic has been employed, and Robertson suggests that this may act deleteriously upon the nervous system. He thinks that it is by no means proved in these cases that the mesenteric vessels cause mechanical obstruction of the duodenum. Lastly, there is the group in which dilatation follows some injury, such as fracture of the cervical spine; it may be the result of paralysis of the abdominal muscles, or be due to oedema spreading up the cord and involving the vagus nucleus in the medulla. Discussing the possibility of the superior mesenteric vessels

causing mechanical obstruction, Robertson thinks that this theory will soon be abandoned. Moreover, it is not his experience that chronic duodenal ileus is cured by duodenoduodenostomy, as it should be if the symptoms were really the result of mechanical obstruction.

### 364. Cartilaginous Tumours of the Larynx.

STCLAIR THOMSON (*Journ. of Laryngol. and Otol.*, January, 1925, p. 1) describes two cases of echondrosis of the larynx. The first was in a woman, aged 53, who gave a history of five years' hoarseness. At that time there was a greyish tumour just appearing below the left cord and oedematous about half the airway. Eight years later there was delatate stridor, and a considerable increase in the size of the tumour. Twelve days later the tumour was removed. The growth on the thyroid cartilage, which proved to be a pure cartilaginous tumour, was removed after dividing the cricoid and two uppermost rings of the trachea, which, with the thyroid cartilage, were partly eroded by the growth. The patient made a perfect recovery and had no further laryngeal symptoms. His second case showed a growth on the posterior aspect of the larynx which was for a time mistaken for tuberculous disease. It was incompletely removed by another surgeon and was shown to consist of cartilage. This patient died some years later after tracheotomy for a very low obstruction of the trachea—apparently some form of recurrence. The author points out that the difficulty in diagnosing these tumours is due to their being almost always subglottic, and in that position difficult of investigation; they are very rare, but they may recur and simulate malignant disease. The author refers to a case reported by Waggett which was at first thought to be syphilis but later proved to be a large chondroma. There was complete immobility of the vocal cord, but no trace of malignancy, showing that a fixed cord may exist in the absence of malignant disease. Another case in StClair Thomson's experience occurred in a woman, aged 45, who had a fixed left cord with a hard, though smaller tumour projecting from below it. A similar cord on that side proved to be perfectly movable. The tumour gave a distinct impression of cartilage, but operation showed it to be a carcinoma, and it was radically removed. E. B. WAGGETT (*ibid.*, p. 27) adds a note on his case mentioned above. When the growth was removed in 1923 the capsule was left intact. Three years later the larynx was entirely filled by a second cartilaginous tumour; when removed it was found to be the size of a hen's egg, and was a true recurrence.

### 365. Acute Primary Typhilitis.

W. A. BRAMS and K. A. MEYER (*Journ. Amer. Med. Assoc.*, February 7th, 1925, p. 436) report two cases of acute typhilitis arising as a primary disease and without being secondary to disease of the appendix or adjacent structures. Though apparently indistinguishable clinically from appendicitis, its recognition after the abdomen is opened is important. In the two cases reported the appendix was found free and healthy, with pns in the right iliac fossa, and a careful search resulted in finding gangrenous and necrotic areas in the caecum. One of the cases three perforated ulcers were found. The authors remark that since immediate operation is essential in either acute appendicitis or acute primary typhilitis, no time should be lost in attempting to establish a differential diagnosis clinically, which, with our present methods of examination, is impossible.

### 366. Surgical Trauma and Syphilis.

W. H. GOECKERMAN (*Surg., Gyn. and Obstet.*, January, 1925, p. 77) discusses the effect of surgical trauma on syphilitic patients with special reference to the healing of the operation wound. Of his 78 cases 50 had received some treatment for syphilis and 28 had not been treated. Only one of the patients in the former group showed any delay in the healing of the wound. The case was one of cancer of the breast in which extensive resection had been performed. The infection was obviously pyogenic, the patient's general resistance was low, and healing was not stimulated by antiseptic treatment. Three patients in the treated group died shortly after operation, but without syphilis being obviously responsible for the fatal issue. In the second group, in which antisyphilitic treatment had not been adopted for various reasons, five patients showed distinct delay in the healing of their wounds, but in three of these a gamma had been included under the mistaken belief that the lesion was an abscess. Goeckerman is of opinion that a considerable number of syphilitic patients are operated on without the surgeon being aware of the infection, and considers that the operative risk could be reduced to a minimum by a routine Wassermann test and proper treatment in certain cases.

722 B.

## Therapeutics.

### 367. Protein Treatment of Coeliac Disease.

L. W. SANER (*Amer. Journ. Dis. Child.*, February, 1925, p. 155) claims to have had excellent results in six consecutive patients with powdered protea milk as the essential diet for many months. He advocates three stages in the dietary treatment. The initial twenty-four hour diet should consist of several level packed tablespoons of powdered protein milk lower than the number of pounds the child weighs. The powdered milk is mixed with a quart of warm sterilized water, and sweetened with 1/4 to 1 gram of saccharine. The mixture passed several times through a fine sieve. The food, gently warmed before serving, is given at four-hourly intervals between 6 a.m. and 6 p.m. The amount of protein tablespoons every five or seven days, regardless of the quality of the stools. The food should thus be gradually increased until the number of tablespoons approximates the number of pounds the child should weigh for his height, or, in stunted, older children, the number of pounds the child should weigh at that age. If there is diarrhoea or tetany Ringer's solution is recommended in place of the plain water in preparation of the food. For the anaemia iron citrate (1 or more grains) may be given intramuscularly twice or three times a week for a month. Precipitated chalk (10 grains to a feed) seems to lessen intestinal fermentation and abdominal distension. This first phase of treatment is continued until the stools, distension, and appetite show distinct improvement. It should never be less than two weeks, and in chronic cases two or three months may be necessary. During the second phase protein milk is supplemented with almost pure protein foods, such as curds of buttermilk or of machine-skimmed milk, scraped lean beef, tongue, and eggs, the increase in the powdered protein milk continuing automatically as outlined in the first phase; this diet should be maintained until the weight approximates to or exceeds the theoretical weight for height. During the third phase carbohydrates are cautiously added, dextrinized flours, arrowroot, crackers, and toasted white bread. This change in diet should never be attempted within the first six weeks of treatment; in severe cases about the third or even the fourth month is usually early enough. If abnormal stools, anorexia, distension of the abdomen, or loss of weight recur, the carbohydrates should be omitted for several weeks or months longer; that is, the diet should revert to the second phase, or if necessary to the first phase, until the alimentary tolerance for carbohydrates has improved.

### 368. Treatment of Whooping-cough.

J. TAILLEUS (*Rev. med. Suisse romande*, January 25th, 1925, p. 3), professor of children's diseases in the University of Lausanne, as the result of over twenty years' experience, comes to the following conclusions: (1) Antiwhooping-cough vaccine does not possess any certain therapeutic value. (2) Adrenalin has no effect in whooping-cough. (3) Sulphuric ether in intramuscular injection is painful, and cannot therefore be employed widely and systematically. Its action is uncertain, sometimes no benefit results, and the relief is at the best only transient. (4) Tailleus recommends bromoforn, which if properly administered has no drawbacks, but is, on the contrary, very constant in its action. He adds that it is easy to give and is always well borne. Not only does it rapidly reduce the number and intensity of the paroxysms, but it increases the appetite and thereby improves the general condition.

### 369. Blood Transfusion in Premature Infants.

P. GUENOT and SEGUX (*Gynecol. et Obstet.*, 1925, xi, 2, p. 111) have had encouraging results from transfusion of blood into five feeble premature infants of from seven to seven and a half months' gestation, with weights of less than 2 kg. and lasting hypothermia, with stationary or diminishing weight. Two of the infants treated were triplets, the third having died the day after birth. Another infant had been born of a moribund phthisical mother and one had melæna. The blood was taken from a donor of the same blood group (usually the mother) and after being citrated was injected slowly (that is, during at least two minutes) into the superior longitudinal sinus at the posterior angle of the anterior fontanelle. In each case the injection was followed by permanent improvement in the body temperature and by progressive increase in weight. The amount injected was 10 to 20 c.c.m., which was calculated to increase the volume of the infant's blood by one-sixth or even more. The other advantages claimed for the treatment are that it increases the leucocytes, which (especially the polymorphs) are present in much smaller proportions in the newborn than in the adult and that certain endocrine substances may be conveyed in the injections.

## Neurology and Psychology.

### 370. Tobacco and the Cerebral Functions.

LÉON BINET (*Presse méd.*, January 31st, 1925, p. 134) observes that recent experiments seem to show that the tobacco smoker absorbs some nicotine. W. Straub states that after smoking one cigar definite traces of nicotine may be found in the urine during an average period of eight hours. Binet states that injections of nicotine produce (1) cerebral congestion, (2) damage to cortical nerve cells, (3) disturbances of memory in animals intoxicated by tobacco smoke. Wertheimer has proved that nicotine is a most powerful cerebral stimulant and produces definite increase in the volume of the brain; in this process the acceleration of the heart's action is an important factor. Georges Guillaud and A. Gy found that a rabbit suffering from chronic tobacco poisoning showed signs of extensive cellular lesions in the liver and cerebral cortex, without vascular, meningeal, or neuroglial injury. P. Matthieu and L. Morklen constructed a labyrinth which white mice had to traverse in order to reach their food or their cage; it was found that normal mice traversed the labyrinth in from twelve to twenty seconds. The animals were intoxicated by being placed in an apparatus through which air circulated at the rate of 1 litre a minute, bringing cigarette smoke from a special burner in which a cigarette was consumed in ten minutes. It was found that after a single stay of ten to fifteen minutes in the apparatus there was no immediate symptom of disturbance. The mouse ate, drank, and traversed the labyrinth as quickly as, or even more quickly than, usual. Later, however, it showed hesitation and made mistakes at the "cross-roads." The animal required a longer time to traverse the accustomed route: after twenty-four to forty-eight hours there was a delay of fifty to a hundred seconds. It did not return to normal until two or three days had passed. Daily repetition of the experiment increased the delay in completing the passage of the labyrinth and prolonged the return to normal conditions. The function of "evocation" appeared to be more disturbed than that of "fixation," as a second passage of the labyrinth was performed in almost normal time immediately after a slow and hesitating passage. Binet considers that these facts indicate that tobacco has a toxic action on the brain.

### 371. Post-encephalitic Parkinsonism.

D. PAULIAN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 12th, 1925, p. 203) states that from the therapeutic standpoint two forms of post-encephalitic Parkinsonism can be distinguished. The first are those in which immobility and rigidity predominate, while in the second there are excitomotor symptoms in addition to rigidity. Treatment by spinal auto-serotherapy has a favourable and even curative influence on the first group, while it has little or no effect on the second. The treatment consists in removing aseptically 40 to 50 c.cm. of blood by venepuncture, collecting the serum in sterile tubes, inactivating it by a temperature of 56°C., and injecting 10 to 15 c.cm. intraspinally after removing an equal quantity of cerebro-spinal fluid. After the injection the patient should remain in the recumbent position for twenty-four hours without a pillow. An injection is made weekly, and three or four are sufficient. Improvement sometimes occurs after the first injection, the earliest favourable sign being the appearance of automatic movements of the arm and trunk in walking. The patients gradually train themselves, become able to run, and salivation diminishes. Of 21 patients treated by this method 5 made a complete recovery, 13 showed a decided improvement, and 3 were failures, but these did not complete the full treatment. No local or general reaction should follow the injection when it is skilfully performed under aseptic conditions.

### 372. Extramedullary Spinal Tumours.

F. HERZOG (*Méd. Klin.*, February 20th, 1925, p. 275) summarizes the clinical features in eight cases of extramedullary spinal tumour in which the diagnosis was confirmed by laminectomy. The symptoms differed from those regarded as typical of extramedullary tumour. In some cases, in which the posterior nerve roots were compressed by the growth, root pains occurred; in other cases, with the growth in a similar position, root pains were absent. In one case the growth did not extend to the posterior roots, but these pains were present; in another parallel case they were absent. Nerve roots distant from the growth may be injured by oedema, irritation, and inflammation, and thus pains may be produced. In all of the cases the onset of the paraparesis was gradual, and the globulin reaction of the cerebro-spinal fluid was increased. One of the patients died soon after the operation, the other seven were practically cured; slight paresis remained, but did not interfere much with the patient's work. None of the eight patients presented the

typical symptoms of extramedullary spinal tumour. The correct diagnosis was made because, by repeated careful examinations, other diseases could with great probability be excluded. Herzog states that in tumours in the dorsal region the upper limit of the sensory disturbances is important, and he recommends the following method of testing sensation. With a soft camel-hair brush the skin is stroked from above downwards (with the same pressure) and the patient asked to say when the sensation changes, without attempting the difficult task of describing the change. A sensory change is thus detected, when a light touch is still felt, and when no change in the sensation for pain or temperature is revealed. When the upper limit of this slight sensory disturbance remains unchanged for weeks or months, though the intensity of the disturbance often increases, then the compressed segment can be localized. Herzog adds that it is not necessary to wait for marked sensory disturbance. By this method a tumour causing only slight compression may be localized, and thus the prospects of successful operation are improved.

### 373. Diagnosis of Diseases of the Pyramidal Tract.

RIMBAUT and BOULET (*Presse méd.*, March 7th, 1925, p. 237) state that Bechterew (1901) discovered that in certain pathological conditions, percussion of the dorsal surface of the tarsus and base of the metatarsus produced flexion of all the toes, except the great toe. Mendel (1904) described the same sign following percussion of the outer side of the proximal half of the instep. To obtain the reflex the patient should lie on a couch with the knee flexed at 90 degrees and the sole in contact with the bed. Normally there is no response on percussion over the cuboid, but occasionally extension of the four outer toes occurs. Various explanations of this have been given: the authors consider that it is due to percussion of the belly of the short extensor of the toes. In certain pathological states percussion over the cuboid causes flexion of the four outer toes. If the interosseous spaces opposite the necks of the metatarsal bones are percussed, the corresponding toes are flexed and slightly abducted (the flexion being limited to one or two toes); this has been called the "interosseous or predorsal reflex" by Sicard and Cantaloube. Schriijver describes a flexion of the toes as occurring in certain psychopathic states, particularly in dementia praecox, on percussion of the lower part of the tibia. Briefly, when percussion over the cuboid causes flexion of the toes the Bechterew-Mendel reflex is positive. It is generally admitted that the reflex indicates a lesion of the pyramidal tract—that is, it is of similar value to Babinski's sign. The authors give the results of the examination of 58 patients suffering from lesions of the pyramidal tract. In 14 cases of hemiplegia, transverse myelitis, and paraplegia after Pott's disease, both Babinski's sign and the tarso-phalangeal reflexes were positive. In 9 cases the former was negative, the latter positive. In these cases it was certain that there was a lesion of the pyramidal tract. The authors conclude that in lesions of cerebral origin the tarso-phalangeal reflex appears late, occurring when the descending degeneration reaches a region in the medulla which has not yet been determined. Thus, Babinski's sign corresponds to a pyramidal lesion, either cerebral or medullary, while the tarso-phalangeal reflex (in an intramedullary lesion) indicates a lesion of the medullary pyramidal tract.

## Obstetrics and Gynaecology.

### 374. An Early Diagnostic Sign of Ectopic Gestation.

Z. BÄNKI (*Zentralbl. f. Gynäk.*, January 17th, 1925, p. 142) emphasizes the importance of diagnosing extrauterine pregnancy, especially for the practitioner who is not a surgeon. He has for many years searched for an early sign which would enable the patient to be treated before the occurrence of severe rupture had lessened her chances of recovery. Pathologists have shown that before rupture takes place there is a period of oozing of blood, when a diagnostic sign would be of great value; this stage occurs in the early weeks of pregnancy. Villi growing in and around the tube destroy it by such a comparatively slow process that tiny haemorrhages occur in the vicinity of the pouch of Douglas for some time before actual rupture takes place. These small bleedings cause first irritation and later definite adhesions, and it is the symptoms caused by these that constitute the first danger signal of the condition. There is undue tenderness of the uterus when it is moved. With two fingers in the posterior fornix the uterus should be pressed upwards as if to press it against the symphysis. If the adhesions mentioned are present the patient experiences an agonizing sensation, while in a normal person there is no pain at all. Bänki has tested this sign in very early cases, and his resulting diagnosis of

a tubal pregnancy was always justified later. Pain on defaecation may also occur. He claims that this sign supersedes the others now in use in that it can be demonstrated before the peritoneal cavity is full of blood, and that in differential diagnosis between abortion or appendicitis it is also of value. There may, he remarks, be fallacies such as acute or chronic parametritis or an abscess in the pouch of Douglas, but these conditions as a rule produce additional symptoms of their own. One other fallacy is that if there has been a previous infection of the pouch of Douglas the uterus will be fixed and the test cannot therefore be elicited.

### 375. Myosarcoma of the Uterus.

K. IMHÄUSER (*Arch. f. Gynäk.*, December 15th, 1924, p. 12), studying a series of operation specimens of uterine myoma, has found about 5 per cent. of cases in which microscopical examination shows the development of sarcoma, and about 3 per cent. other cases in which such an examination leads to grave suspicion. He names the following clinical signs as pointing to the possibility of a myoma having become sarcomatous: (1) severe haemorrhage in the menopause, although this rarely, if ever, occurs in other than submucous tumours; (2) pain which is independent of menstruation; (3) persistence of symptoms after radiation; (4) a specially soft consistency of the tumour; (5) rapid increase in size of a myoma; and (6) disproportion between the size of the tumour and its local symptoms. Microscopical examination is essential for the sure diagnosis of myosarcoma. The most important criteria are, in his opinion, an increased richness in cells, diminution of intercellular substance, and disappearance of the typical arrangement in bundles, dissimilarity in size and irregularity in form of the cells, and more especially of their nuclei; the presence of mitoses in large numbers, of which some are atypical; the recognition of multinucleate cells; and variation in the intensity of staining of the nuclei. He adds that considerable judgement is required in forming an opinion, and none of the signs enumerated is of itself conclusive.

### 376. Pregnancy and Myeloid Leukaemia.

J. O. BOWER and J. H. CLARK (*Amer. Journ. Obstet. and Gyn.*, February, 1925, p. 207) have traced in the literature fifteen cases of coexisting pregnancy and myeloid leukaemia, and add two new cases. In only four cases did the leukaemia precede pregnancy. They state that the accepted therapeutic procedure of inducing abortion early during pregnancy finds support in the fact that almost every patient who has been allowed to go to term or near it has died within forty hours after delivery. They note that no malformations have been found in the offspring of leukaemic mothers who have had radium applications during pregnancy. The child in their own case had a normal blood picture but died at the age of 3 weeks. Sängner and Askanazy by examination of the blood of the umbilical cord have shown that the erythrocytes of leukaemic mothers do not penetrate through the placenta to the foetus.

### 377. Puerperal Infection by Spirochaetes.

E. PHILIPP (*Arch. f. Gynäk.*, December 15th, 1924, p. 268) states that saprophytic spirochaetes are not infrequently found as part of the vaginal flora; he has found them present in small numbers in about 5 per cent. of recently delivered women. They may be found in the vagina or uterine cavity, and may be especially abundant in the cervical secretion. In exceptional cases the number of spirochaetes found exceeds that of all other organisms, and in three such cases the author has found a somewhat characteristic clinical picture. During the puerperium an oedema of the labia minora is noted and the vaginal wall and portio cervicalis show multiple erosions and superficial necrotic patches; the discharge is very abundant, thin, and watery, without being offensive. There is some pyrexia, with little general disturbance, and the inflammation takes a benign course, resolving spontaneously in four or five days. It is concluded that in certain cases the saprophytic organisms are capable of taking on pathogenic properties.

## Pathology.

### 378. Cutaneous Vaccination against *B. abortus*.

It is well known to laboratory workers that *B. melitensis* is a dangerous organism to work with, and in several cases infection has resulted from the manipulation of cultures. H. VIOLLE (*C. R. Soc. de Biologie*, February 20th, 1925, p. 421) believes this is the result of contamination of the skin with the bacilli. Acting on this idea, he has made experiments with the *B. abortus*, Bang—the organism responsible for epizootic abortion in cattle—which is similar to *B. melitensis*

very closely, to determine whether it is possible to infect guinea-pigs by rubbing the organism into the skin. A three day old culture on agar was scraped off and mixed with lard; this mixture was then rubbed into the depilated but non-scarified skin of the abdomen. Both animals treated in this way died one month after inoculation, having lost considerably in weight. Apart from general emaciation and a slight increase in the size of the liver and spleen, there was no gross pathological change, but bacilli were found in all the organs—liver, spleen, kidneys, brain, testicles—and cultures on agar yielded a pure culture of *B. abortus*, which was agglutinated by a specific antiserum. In another experiment only 1/20 of an agar slope was used for inoculation; of the two guinea-pigs treated, one survived in spite of a loss in weight, whereas the other died in twenty days, and was found at autopsy to contain the specific bacilli in the viscera. An attempt to vaccinate guinea-pigs was then made. An agar slope culture was killed by heating at 60°C. for one hour, mixed with lard, and rubbed into the depilated abdominal skin on three occasions at four days' interval. Inoculation of a living culture of the organism by the same route had no effect; the animals lived for three months without losing weight, and when killed at the end of this time their organs were found to be free from the bacillus. The author claims to have shown that skin infection is possible with this organism, and that cutaneous vaccination with dead cultures is able to protect against living organisms rubbed into the skin.

### 379. Serodiagnostics in Tuberculosis.

F. KLEMPERER and A. SALOMON (*Med. Klin.*, January 25th, 1925, p. 121) review the literature on the subject of serodiagnostics in tuberculosis. During recent years many observers have endeavoured to devise laboratory methods to make the diagnosis of tuberculosis more certain. In particular Wassermann and Besredka have used antigens, while Sachs and Klopstock have described a flocculation (leithin) test. Klemperer and Salomon have made extensive trials with all these methods. They divided the patients into three classes—namely: (1) Definite tuberculosis, including acute infections and cases in which tubercle bacilli had been found. (2) Patients in whom tuberculosis was not suspected—either healthy controls or cases of organic disease, including diseases of the heart, kidneys, liver, or nervous system. (3) Cases of suspected tuberculosis and of surgical tuberculosis, including tuberculous diseases of the eye. The percentage of positive results varied greatly when the methods of Wassermann, Besredka, and of Sachs' and Klopstock were contrasted. Klemperer and Salomon consider that the Wassermann tuberculosis serum reaction is positive in approximately 75 per cent. of cases of tuberculosis. On the other hand, Schlossberger and Hartoch have reported recently that in cases of active tuberculosis they obtained 70.6 per cent. positive results, while among the "negative" controls the positive results were as high as 29.2 per cent. In addition to the divergent results obtained by Klemperer and Salomon they found that the degree of positive reaction bore no relation to the severity of the clinical symptoms. It is possible that further research will lead to greater uniformity in the results obtained with antigens and that the respective merits of antigens and of the flocculation test will be more clearly shown; at present they think that the latter appears to be the more uncertain. The authors conclude by remarking that Wassermann considered that there was an analogy between tuberculosis and syphilis, the brilliant success of his reaction in the latter having led him to anticipate a similar result in tuberculosis. They point out that obviously no true analogy exists, nor do positive reactions in tuberculosis give similar indications in regard to treatment to that given by the Wassermann reaction in syphilis.

### 380. Sterilization with Burning Spirit.

H. MAYSER (*Zentralbl. f. Bakt.*, February 18th, 1925, p. 238) has made some experiments to test the efficacy of the common laboratory procedure of sterilizing objects by pouring spirit over them and then flaming them. The object to be tested was smeared over with some culture from an agar slope, or was immersed in a broth culture and allowed to dry; the organisms used were *B. anthracis* and *B. typhosus*. When dry some spirit was poured on, ignited, and cultures made in bouillon. Mayser found that flat surfaces, such as brass wire, glass rods, and spoons could not be sterilized thus. Hollow articles, on the other hand, varied in accordance with the heat-conducting nature of the material of which they were made. Basins of wood, a substance which has a very low heat-conducting power, were not rendered sterile even after the spirit had been burning for a minute, whereas glass, porcelain, or metal basins of medium and high heat-conducting power were sterilized by this means. These experiments indicated that it was not the flame itself which disinfected, but the heat generated by it.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### Sciatica.

381. P. SCHUSTER (*Klin. Woch.*, February 12th, 1925, p. 316) holds that the diagnosis of sciatica is justified only when (1) the pain is limited to the distribution of the sciatic nerve, its roots or one of its branches, and (2) when objective results of examination are negative—that is, when no signs of disease of joints, bones, or other parts, or signs of neuritis can be detected. True sciatica is unilateral; bilateral sciatica should awaken suspicions of disease of the spinal cord, cauda equina, or its membranes. In the treatment rest in bed, though always worthy of trial, can usually be secured only in severe cases. Warm applications, such as hot sandbags, may be employed at first, with cupping or treatments which produce hyperaemia of the skin. If these fail diathermy may be useful. Of the electrical methods a constant current of 5 to 10 milliamperes, with stable electrodes, is most likely to be of service. In recent years, Schuster remarks, very good results have been obtained by treatment with high frequency currents, or x-ray treatment of nerve roots, or a combination of these methods with diathermy. The best results have been obtained by injections into the nerve sheath, or by paraneural injections. Substances which may cause bad effects should not be used, and therefore alcohol especially should not be injected. The author has usually obtained good results by the injection of 0.5 to 1 or 2 per cent. solutions of novocain and similar substances. These were injected with a large quantity of fluid (100 or 150 c.c.m.), care being taken that the total amount of novocain or eucaino injected was not too large. The paraneural injection is advised for those who are inexperienced in making injections into the nerve. Antipyretic drugs, codain suppositories, and aspirin or salicylate preparations should also be employed. In all cases, Schuster adds, it is important to obtain a free, easy evacuation of the bowels, and, if possible, dolulant diarrhoea.

382. G. KAHLMEIER (*Hygiea*, January 15th, 1925, p. 1) traces the development of the x-ray treatment of sciatica since Goeth in 1837 gave this treatment with success to an old man who had suffered for ten years from trigeminal neuralgia. Since then this treatment has achieved many successes both in trigeminal neuralgia and in sciatica, but no scientific explanation has yet been given of its action. During the past three years the author has treated 33 cases of sciatica in the x-ray department of the Sabbatsberg Hospital. There were 16 men and 17 women; in 8 cases the disease was bilateral. The duration of symptoms before the institution of this treatment ranged from one month to three years, and most of the cases were severe and had proved refractory to other treatment. Sixteen of the patients had been treated in hospital, 13 had been given injections of saline solution, and only one patient had received no previous treatment. In practically every case the x-ray treatment was not supplemented by other measures apart from anodyne drugs and, in 18 cases, rest in bed. In 12 of the 33 cases, the sciatica was probably of a static-functional character, being associated with such conditions as flat-foot and arthritis of the knee which predispose to, and probably cause, sciatica. After giving an account of the technique of the radiation, and stating that the observation period since the termination of the treatment ranged from half a year to three years, the author reviews his results. In 18 cases the pain ceased within a few weeks of the completion of this treatment and did not recur, although in as many as 10 of these cases the observation period was more than two years. In 10 other cases this treatment was followed by improvement which, in some cases, was succeeded by complete recovery under some other treatment. In 5 cases there was no improvement. The number of successes achieved among the static-functional cases was comparatively small, and the patients whose sciatica had lasted long responded least satisfactorily on the whole. The author's considered verdict on this treatment is favourable.

383. The Diagnosis of Mild Forms of Pancreatitis. G. KATZ (*Klin. Woch.*, February 12th, 1925, p. 289) considers that the diagnosis of pancreatitis depends too much on laboratory methods, and discusses the clinical side of the problem. Apart from the well known signs of acute necrosis of the pancreas, and pancreatic diarrhoea, other symptoms of pancreatic affection are few. Katz believes, however, that pain in the upper part of the abdomen, radiating to the

left side, is always suggestive of pancreatic affection in the absence of definite indications of gastric ulcer, renal stone, and recent infarct in the spleen. Pain due to pancreatic affection extends to the left in the region of the spleen and kidney, and along the arch of the ribs: it is often most severe in the back on the left side and may be permanent or paroxysmal. With pain in this region the special tests for pancreatic disease should be made, with a view to detecting starch in the blood or urine, lipasaemia, fragments of striated muscle fibres in the faeces, dyspancreatic motions, and more rarely glycosuria. In addition to the extension of the pain to the left, in many cases Katz thinks that a very important sign is a left-sided zone of hyperaesthesia of the skin (Head's zone). On examination with a pin a hypersensitive half-segment, or portion thereof, is found. It is often most distinct in the back near the tenth to the twelfth dorsal vertebral spaces and corresponding with the eighth dorsal segment. A similar hypersensitive zone can often be detected anteriorly in the upper part of the abdomen, and in the flank. These left-sided Head's zones are frequent and often very distinct in pancreatitis, more so than in any other disease of the abdominal organs. A region hypersensitive to light percussion may usually be detected also in the upper part of the abdomen, on the left side. Six cases are recorded showing the value of these symptoms as indications of mild forms of pancreatitis.

### 284. Orchitis and Abdominal Pain in Serum Sickness.

E. W. GOODALL (*Brit. Journ. Child. Dis.*, January-March, 1925, p. 39) relates the case of a boy, aged 10, who had been given 33,000 units of diphtheria antitoxin in three doses for a severe attack of faucial and nasal diphtheria. Urticaria appeared on the abdomen at the site of one of the injections six days later, and after another six days he complained of pain in the left iliac fossa, but nothing abnormal could be detected on palpation. The following day he had pain in the knees, elbows, and wrists, and the temperature rose to 100.6°. The next day he complained of pain in both testes, which were slightly swollen and tender; the scrotum was red as if slightly inflamed. The pain in the abdomen and testes gradually disappeared after lasting for twelve days, during which an erythematous rash on the trunk and limbs and irregular pyrexia were present. Similar cases of orchitis and abdominal pain during serum sickness have been reported by French observers, but are very rare. (See *BRITISH MEDICAL JOURNAL*, March 15th, 1924, p. 482.)

## Surgery.

### 385. Spontaneous Perirenal Haematoma.

F. GRECO (*Arch. Ital. di Chir.*, January, 1925, p. 1), who records 61 cases of non-traumatic perirenal haematoma as well as 2 of his own in a man aged 54 and a woman aged 43, states that this condition was first described by Wunderlich in 1856 under the name of "apoplexy of the renal capsule." The male sex is most frequently attacked; of 55 cases in which the sex was stated 35 were males and 20 females. Most cases occur between the ages of 18 and 60. As regards the etiology Coccen has distinguished a primary or essential form due to inflammatory or degenerative lesions of the vessels, haemophilia, nephritis, renal sclerosis, etc., from a secondary form due to tumours, renal tuberculosis, rupture of the vessels of the hilum, etc. The three principal symptoms as described by Wunderlich are sudden and violent pain in the lumbar region, signs of internal haemorrhage, and the rapid formation of a retroperitoneal tumour. This triad of symptoms closely resembles the clinical picture of extrauterine pregnancy, which is the most likely diagnosis to be made if the patient is a woman. Fever is not constant but frequent, ranging from 102.2° to 104°. In some cases, however, the temperature is subnormal owing to a state of shock. Examination of the urine yields different results according to the state of the kidney, the urine being sometimes perfectly normal, while in others there is slight albuminuria or casts. The presence of blood may vary in degree from a few red cells visible on microscopic examination to an actual haematuria. Symptoms of peritonitis, such as vomiting, meteorism, muscular rigidity and constipation are particularly marked in those cases in which there is an effusion of blood into the peritoneal cavity or an extensive retroperitoneal suffusion. Ecchymoses in the lumbar region and abdominal wall are uncommon, their presence being of

399. **Insulin Treatment for Boils.**  
 STÜRMER (*Klin. Woch.*, Moreh 5th, 1925, p. 477) briefly records the result of the treatment of boils with insulin injections. He bases the treatment on the fact that diabetic patients boils and carbuncles heal rapidly under the influence of insulin; and on the fact that staphylococci made worse by the administration of sugar. In diabetic patients the author has tried the insulin treatment with good results. After the first or second injection the patients declared that the throbbing pain and irritation diminished; on the second day, in every case, visible improvement occurred. Even in a case of boils of six months' duration rapid healing followed insulin treatment. Encouraged by these results the author tried the insulin treatment in pyoderma, and in some cases found it of much service.

990. The Indications for Salvarsan Sulphoxylate.

T. H. FABRY (*Urol. and Cut. Rev.*, January, 1925, p. 1) states that salvarsan sulphoxylate was introduced into the therapeutics of syphilis by Ehrlich's successor, Kolle. Its advantages over the older preparations of solverson are said to be that the preparation is put up in convenient form as ampoules, is soluble and ready for immediate use, that it is potent. The caustic action of the sulphoxylate is also less than that of any other solverson preparation. It is commended by Fabry in the following conditions: (1) in subsequent treatment of the following conditions: (1) in syphilis; (2) tertiary syphilis; (3) general paralysis and Wassermann reaction; (4) framboesia and malaria. The dose is two to four weeks after disappearance of symptoms. The dose is 8, 10, or 12 c.c.m., at intervals between the injections should never be less than three weeks in the various stages of syphilis. The course, and there should never be more than four injections, after which there should be a pause of two or three months in the salvarsan treatment. A 5 per cent. solution is used, so that 10 c.c.m. contains 0.5 g. of sulphoxylate in framboesia and malaria the first injection should be given from 0.15 to 3 c.c.m. per kilo of body weight. Infants should be given every fourteen days. The indications for sulphoxylate are the same as for the preparations of salvarsan—namely, pronounced cardiac dilatation, aneurysm, and renal and hepatic disease.

[illegible]

337. **Partial Rupture of the Colon.** (Zentralbl. f. Chir., February 14th, 1925, p. 349) describes the following case: A man, aged 25, while using a lever to raise a heavy stone, felt a sudden severe pain in the abdomen "as though something was torn." Finding that the pain persisted and was increased by walking, he was admitted to hospital five hours after the onset of pain. There was marked rigidity of the whole of the lower part of the abdominal wall, and the lightest pressure was painful. In the left iliac fossa there was an area of absolute dullness. He could urinate spontaneously, but the effort caused hypogastric pain. The urine was normal, the pulse 90, the tongue moist and coated, and the rectal temperature 99.3°F. As the symptoms persisted, and it appeared probable that there was some intra-abdominal injury, median infraumbilical laparotomy was performed one hour after admission. On opening the peritoneum, fresh liquid blood was seen between the coils of intestine. The bladder was uninjured. A linear longitudinal laceration of the serous and mesocolic coats was found in the lower portion of the sigmoid, just above its entrance into the rectum. The tear was 2 inches long, and was opposite the attachment of the mesosigmoid. Notwithstanding its unsupported position, the mucosa was intact, but it bulged through the laceration. Around the laceration a haematoma containing bright red arterial blood, and measuring 2½ by 1½ inches, had formed. The edges of the laceration were adherent and everted. The rent in the serous and muscular coats was closed with sutures and the peritoneal layer of the peritoneum was sutured over the area of the haematoma. The patient was quite well twenty-two weeks

## 391. Potassium Acetate in Post-operative Retention of Urine.

D. GALL (*Zentralbl. f. Chir.*, January 17th, 1925, p. 123) states that Reimer, from observations on 49 cases, came to the conclusion that a solution of potassium acetate acted as a specific in post-operative retention of urine. The simplicity of the method, its experimental basis, and the results obtained by Reimer induced Gall to try it in the surgical clinic of the Medical Institute at Ekaterinoslav, where 31 patients were selected in whom retention of urine set in from ten to fourteen hours after operation under chloroform preceded by injection of morphine for the following conditions: piles 14 cases, inguinal hernia 10 cases, appendicitis 4 cases, gastro-enterostomy 2 cases, nephrectomy 1 case. The results were as follows: Only four patients in whom spontaneous evacuation of the bladder occurred reacted to the drug after two to six doses. All the rest had to be catheterized in spite of administration of the drug every three hours. Gall concludes that potassium acetate cannot be regarded as a specific for post-operative retention, for though Reimer was successful in 100 per cent. of his cases Gall obtained favorable results in only 13 per cent.

## 392. Treatment of Pleural Effusion by Sodium Citrate.

A. COYON and P. MARTY (*Bull. Soc. de Théor.*, January 14th, 1925, p. 13) state that intrapleural injection of sodium citrate, while of little use in the pleural effusion of cardiac disease, may be of value in the treatment of chronic empyema with production of fibrinous clots, as it considerably facilitates escape of the fluid. After radiological estimation of the amount of fluid left in the pleural cavity, 2 to 10 c.cm. of a varnished 10 per cent. solution of sodium citrate is injected. In cases of sero-fibrinous effusion the strength of the solution ranged from 10 to 30 per cent. according to the amount of fluid left behind. The authors suggest that the stagnant effusion in artificial pneumothorax would probably be benefited by injection of the sodium citrate solution, which might also be employed in some cases of pericardial or ascitic effusion with the object of preventing adhesions or obviating the formation of fibrinous deposits.

## Ophthalmology.

## 393. Associated Movements.

E. A. CARMICHAEL and M. CRITCHLEY (*Brit. Journ. Ophthalmol.*, February, 1925, p. 49) in this paper discuss the curious phenomenon of associated movements. The best known example of a movement associated with the contraction of an extrinsic eye or eyelid muscle is the "jaw-winking reflex." The authors have noted six further types of associated movements. The "oculo-aural movement" consists in the helix of each pinna becoming rotated backwards and inwards towards the mastoid when the eyes are fully deviated laterally. The movement is slow and deliberate; it is a bilateral phenomenon, the wider excursion occurring in the contralateral ear. The "oculo-frontalis movement" is the name given to the depression of the contralateral eyebrow and the raising of the homolateral eyebrow on deviating the eyes laterally. The "oculo-lingual movement" implies the tongue pointing to the homolateral side on deviation of the eyes. The "oculo-mandibular movement" is a combined protrusion and deviation of the mandible to the contralateral side if the eyes are rapidly deviated first to one side and then to the other. In the "orbiculo-stapedial movement" there is unilateral blepharospasm with buzzing noises in the homolateral ear. The "oculo-nasal movement" denotes dilatation of the nostrils on extreme deviation of the eyes. The authors suggest that there is a phylogenetic origin for these movements.

## 394. Glioma of the Retina.

CABANNES, MONToux, and GUINAUDAU (*Gaz. hebdom. Sci. méd. de Bordeaux*, March 8th, 1925, p. 153) state that four stages may be distinguished in the course of glioma of the retina. In the first stage there are no symptoms of irritation, but merely a diminution of vision, rapidly ending in blindness. The second stage begins with increase of pressure, the eye becoming injected, painful, and hard. The third stage is that of perforation of the eyeball, the new growth escaping from the eye at various points, especially in the region of the optic nerve and cornea. The fourth stage is that of generalization, the glioma invading the brain by the optic nerve. Metastases sometimes occur in the lymphatic glands and viscera, especially the liver. Death is due to cachexia or invasion of the brain. The authors remark that it is obvious that operation, x-rays, and radium cannot be of any avail in the last stage, which is invariably fatal, but these methods may cause transient

improvement or in rare instances produce a permanent cure when applied during the other three stages. For a long time enucleation and exenteration were the only methods of treatment of glioma of the retina. In favorable cases—that is to say, in the preglaucomatous stage—enucleation, with as complete excision of the optic nerve as possible, has produced some permanent cures. Exenteration of the orbit is indicated in the glaucomatous stage, in which there is some hope of a cure, though recurrences are frequent. They are also the rule in the third stage, when exenteration should also be tried. Of 26 cases of glioma of the retina collected by the authors in which x-ray treatment was used, only 4 were successful. As a rule the method has been employed without previous enucleation. Radium therapy has been used in only 4 cases, reported by Chaso (1910), Foyales (1921), Keys (1922), and Cabannes and Réchon (1925) respectively, in which the results were better, especially when radium was combined with surgical treatment.

## 395. Inflammatory Swellings simulating Dacryocystitis.

J. GREEN, jun. (*Arch. Ophthalmol.*, January, 1925, p. 68) draws attention to the fact that inflammatory swellings over the site of the lacrimal sac are not due necessarily to acute primary inflammation of the sac. In the first place the intimate relation of the anterior ethmoidal cells to the lacrimal fossa, as pointed out by Whitnall, provides a not infrequent route for extension of purulent inflammation of these cells to the surface. There is a group of cases in which inflammation extends from the mucous membrane of the nose to the neighbourhood of the tear sac. In these cases the lacrimal canal is permeable, and the sac is not at first affected, though it usually becomes so later. In some cases the orifices of the sac are closed by pressure from pus externally, the pus coming from an empyema in one of the nasal sinuses. Occasionally purulent collections in the deeper parts of the orbit may gravitate to the region of the sac, simulating a lacrimal abscess. Funnels over the site of the lacrimal sac is, Green thinks, more common than ophthalmologists suppose. A gummatous inflammation at the inner canthus may rarely occur. Finally, it is probable that, on occasion, a localized focus of osteomyelitis of the superior maxilla may give rise to a subperiosteal abscess which may form at the usual site of a lacrimal abscess.

## 396. Ocular Phenomena in Acromegaly.

W. I. LILLIE (*Amer. Journ. Ophthalmol.*, January, 1925, p. 32) discusses the ocular findings and their relation to the sella turcica in 50 cases of acromegaly. In 13 of the 50 cases the sella turcica and ocular findings were normal so far as chiasmal involvement was concerned. In 21 cases x-ray examination showed enlargement of the sella turcica with erosion of the posterior clinoids, but with no ocular changes characteristic of chiasmal involvement. In 16 cases there were definite ocular changes characteristic of chiasmal involvement with enlargement of the sella turcica and erosion of the posterior clinoids. Sixty-eight per cent. of all the cases of this series of acromegalic patients were normal from the ophthalmological point of view so far as any chiasmal changes were concerned.

## Obstetrics and Gynaecology.

## 397.

## Hydatid Mole.

R. REMMELTS (*Nederl. Tijdschr. v. Geneesk.*, November 22nd, 1924, p. 2584) gives the following statistics of 44 cases of hydatid mole which were treated in the Amsterdam University Women's Clinic between 1838 and August, 1924. Since about 1,700 births and some hundred miscarriages occur in this clinic every year the frequency of hydatid mole may be estimated as 1 in every 2,000 pregnancies. The ages of the patients were as follows: under 20, 4; between 20 and 30, 21; between 30 and 40, 9; between 40 and 50, 9; over 50, 1. Eight of the patients were primiparae, and the rest had given birth to from two to twenty children. There was no example in the Amsterdam clinic of one woman having had repeated molar pregnancies, but Fritsch has reported a case of four molar pregnancies in the same woman, and Demaire has recorded an example of a woman who had a molar pregnancy six times in the course of eight years. The relation of molar pregnancy to child-bearing is shown by the following classification of 34 Amsterdam cases in which the data were available: (1) in 15 multiparae the hydatid mole represented the last pregnancy; (2) in 5 cases the molar pregnancy was succeeded by the birth of from one to ten normal children in subsequent labours; (3) in 13 cases the molar pregnancy was both preceded and followed by normal pregnancies; (4) in only one instance did the molar pregnancy represent the only time that the woman had been pregnant.

Hydatid mole is commoner in unusually fertile women, as the 34 patients had given birth to a total of 201 children in addition to miscarriages and molar pregnancies, so that on an average each woman had had at least seven pregnancies. In view of the fact that hydatid mole has been attributed by Lemaire to defective ovarian function the menstrual history of the 44 patients was investigated with the following results: in 25 menstruation was regular and normal in amount; in 5 the periods were regular but scanty; in 5 there was considerable loss of blood; in 3 menstruation was irregular; and in 5 no details were available. The age when menstruation commenced gave no support to Lemaire's theory, as in the great majority of cases menstruation started at the usual age. Out of 28 cases in which the size of the uterus was compared with the duration of pregnancy, in 15, hypomeresis was found to be larger than usual for the period of pregnancy in 19, and smaller in 8 its size corresponded with the duration of pregnancy. In accordance with the experience of other observers the duration of pregnancy in the Amsterdam cases ranged from one to thirteen months. A few cases are on record in which a mole has been retained in the uterus as long as twelve or thirteen months. Toxic symptoms were observed in a large proportion of cases—namely, albuminuria in 15, hypomeresis in 2, and icterus in 1. In 6 cases the presence of an ovarian cyst was diagnosed. Of the 44 cases 35 recovered without any treatment beyond spontaneous or artificial emptying of the uterus. In one case owing to a mistaken diagnosis total hysterectomy was performed. One patient died of puerperal septicaemia and three of diseases unconnected with the mole—namely, placenta praevia, pulmonary tuberculosis, and Bright's disease. The remaining four cases developed chorion-epithelioma malignum. Two of these died without operation, and of two on whom operation was performed one recovered and the other died five days after the operation. Only 17 of the patients had a completely afebrile puerperium; in 5 the temperature was above 104° in 10 between 102.2° and 104°, and in 10 between 100.4° and 102.2°.

398.

#### Treatment of Cancer of the Cervix.

F. DAELS and P. DE BACKER (*Nederl. Tijdschr. v. Geneesk.*, January 17th, 1925, p. 229) state that the number of operable cases of cancer of the cervix varies with different observers from 5 to 45 per cent., the operation mortality from 15 to 35 per cent., and the recovery rate from 5.8 to 47.8 per cent. The authors' treatment is as follows. They first employ x-rays in two or three fields—namely, the abdominal, dorsal, and, if possible, the vaginal—so as to disinfect the cancer lesion. Three or four days later radium is introduced into the cervix and vaginal fornices. If there is no fever and the lesion appears clean, Wertheim's radium method is employed. If, on the other hand, fever is present and the lesion is breaking down, they advise waiting four or five weeks until the fever has subsided and the lesion have become clean before using the Wertheim method. The doses employed ranged from 60 to 70 millicuries.

399.

#### Treatment of Puerperal Uterine Inversion.

L. COURTY (*Bull. Soc. d'Obstet. et de Gynecol. de Paris*, 1925, 2, p. 158) observes that the diversity of opinion regarding treatment of irreducible acute puerperal inversion of the uterus is not remarkable, since few surgeons have treated more than one case of a complication which occurs, according to Ribemont-Dessaignes, in only one labour among 100,000. The operation of Kustner in the deadweight of the uterus is presence of a large friable uterine posterior hysterotomy may cause considerable haemorrhage and leaves a long incision to be sutured. Moreover, the uterus has to be replaced through a small colpotomy opening—a manoeuvre which may take up much time and cause considerable shock. Courty considers this operation inapplicable in cases of recent inversion; if attempt at manual reduction fails, he prefers an expectant course, practising hysterectomy by the vaginal route if severe haemorrhage or infection occurs.

### Pathology.

#### The Heat Resistance of the Tubercle Bacillus.

J.-L. OERSKOV (*C. R. Soc. de Biologie*, February 13th, 1925, p. 400) has made investigations to ascertain the thermal death point of tubercle bacilli in milk. In most work of this kind it is usual to test the survival of the bacilli by injecting the milk, after heating, into guinea-pigs. The results obtained in this manner have generally agreed fairly closely in showing that the organisms are killed by a temperature of 63° C. in twenty minutes. The author questions the value of this method. Not only are guinea-pigs expensive, but there is some evidence that the virulence of bacteria is destroyed by

a lower degree of heat than that necessary to kill them; in this way tubercle bacilli which had received a sublethal application of heat, though still alive, might fail to give rise to disease on injection into susceptible animals. To avoid this possible fallacy he has substituted cultivation in tubercle inoculation. Milk was infected heavily with tubercle bacilli of human type, distributed into glass tubes and heated at a temperature of 63° C. in a water-bath. After varying intervals 7 or 8 drops of the milk were inoculated into cultures of medium, five tubes being used in each case. The cultures were examined for evidence of growth after four, six, and twelve weeks. After four weeks there was growth in tubes which had been inoculated with tubercle bacilli heated for thirty minutes; after six weeks in tubes containing tubercle bacilli heated for forty minutes. These numbers in milk.

#### 401. The Influence of Age on Susceptibility to Infection.

A SERIES of experiments has been made by C. EGUCHI (*Zeit. f. Hyg. u. Infektionskrankh.*, 1925, 104, p. 241) to determine the relative susceptibility of young and adult animals to infection. In the first series young mice from one to five weeks old were placed with their mothers in glass cages, four or six animals in a cage. A similar series of adult mice, varying in weight from 16 to 24 grams, were likewise placed in cages. The animals were then fed by means of a capillary pipette with a saline suspension of *B. typhi murium*, an organism which is naturally pathogenic to mice. Usugasa strain, the Ellinger strain, it was found that the specific death rate amongst the young mice was 69 per cent., whereas that amongst the adult mice was only 33 per cent. With another strain, Topley's strain, the difference was even more marked; in this case the specific mortality amongst twelve young mice was 100 per cent., amongst eighteen adult mice it was nil. Eguchi concludes that there is no doubt from these experiments that young mice are very much more susceptible to this organism than are adult mice. In a second series of experiments guinea-pigs were used, fed with the Ellinger strain. The results were similar to those obtained with mice, though higher doses had to be given to adult animals fed in a like manner not a single one died. This experiment indicates that a species of animal, such as the guinea-pig, which in the fully grown state is comparatively resistant to infection with this organism, is comparatively susceptible when newly born. In a third series of experiments young kittens a few days old were infected with either the vegetative or the oocyst form of dysentery bacillus, and were compared with adult cats similarly infected. Of the kittens 40 per cent. out of a total of twenty-two developed dysentery, whereas of the cats only 8.6 per cent. of a total of twenty-two developed the disease. From these experiments that young animals are more susceptible to alimentary infection than older ones, and that this difference is due to a deficiency in the defence mechanism of the intestinal mucosa in the younger animals.

402.

#### Stimulants to Bacterial Variation.

A. EASTWOOD (*Journ. Hygiene*, December 18th, 1924, p. 317) argues that immunity is not completely explained by antibody reactions since other factors have to be considered, one of which is the influence of stimuli upon the vital capacities of bacteria. Transmissible bacterial variation is apparently due to a stimulus acting upon the growing bacterial cell and resulting in the splitting off of daughter cells which, being non-viable, undergo autolysis. Transmissible autolysis is not, he thinks, due to a stimulus *sui generis*, but is merely an incident in the general phenomenon of bacterial variation. In pure culture the secretions of bacteria, by stimulating, favourably or unfavourably upon their growth, and are to be distinguished from the stimulants of animal origin which act either themselves. Eastwood suggests that one aspect of the difference between natural immunity and susceptible species, he interprets as due to differences in the stimuli inherent in the particular animal species and to consequent differences in their effects upon the particular bacterial species. He explains the acquired immunity of a susceptible animal as being the result of a change in the animal's stimulant action from one favourable to bacterial growth to one which is adverse, and he points out that leucocytes are one of the sources of material cells and an enzyme action on the growth capacities of living and dead cells. A stimulus other than a food cause incorporated as part of the structure of the cell.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 403. Erythema Scarlatiniforme in Epidemic Encephalitis Lethargica.

J. SABRAZÈS, FLYE SAINT-MARIE, and RAYLAC (*Gaz. Hebdomadaire de Bordeaux*, February 8th, 1925, p. 84) record the case of a girl, aged 16, in whom an attack of epidemic encephalitis commenced with diplopia. Five days after the onset she developed a scarlatiniform eruption and a painless infection of the fauces. The erythema was transient, no desquamation occurred, and the patient entered the lethargic stage of the disease, which lasted eleven days. In convalescence there was a marked paralysis of accommodation. The patient was treated for a fortnight by daily intravenous injections of sodium salicylate (1 gram daily at first, and later 2 grams), and finally complete recovery occurred. Erythema scarlatiniforme differs haematologically from scarlet fever in that few or no eosinophils are present, and hardly any basophil inclusion bodies are seen in the polymorphonuclear leucocytes. Sometimes the eruption is morbilliform, as in the cases of Buzzard, Lereboullet and Mouzon, Althout, Bédard, and Smith, and suggests measles or rubella. In other cases the rash is papular or purpuric, as in cerebrospinal meningitis (Salntou, Achard, H. Roger). The eruption, accompanied by an exanthem at the onset of epidemic encephalitis, should be compared with the similar eruption noted in epidemic poliomyelitis, which, according to Regan, is found in 10 per cent. of some epidemics.

### 404. Hearing Apparatus for the Deaf.

C. HVIDT (*Ugeskrift for Læger*, February 5th, 1925, p. 127) gives an account of an institution, started in December, 1917, for providing and testing apparatus for the deaf. Four main groups of contrivances have been investigated, the radiophone, the hearing tube, the ear trumpet, and an electrical apparatus including a microphone being characteristic representatives of these groups. Of the 368 patients tested 168 suffered from middle-ear disease, 121 from otosclerosis, and 79 from disease of the internal ear. Of the patients with middle-ear disease 6 per cent. derived no benefit from any apparatus, 5 per cent. obtained most help from hearing tubes, 44 per cent. from trumpets, and 45 per cent. from electrical apparatus. Of the patients suffering from otosclerosis 10 per cent. derived no benefit from any apparatus, 4 per cent. obtained most help from hearing tubes, 46 per cent. from trumpets, and 40 per cent. from electrical apparatus. Of patients with internal-ear disease 14 per cent. derived no benefit from any apparatus, 15 per cent. obtained most help from hearing tubes, 52 per cent. from trumpets, and 19 per cent. from electrical apparatus. It was observed that in most cases of deafness due to old age trumpets and ear tubes were more effective than electrical apparatus, which was of little value; this aid to hearing requires a certain amount of application and practice. The author notes that the high percentage of successes (45 per cent.) achieved by him with electrical apparatus in cases of middle-ear disease does not tally with the experiences of Schriener of Alexander's clinic in Vienna, where, in this class of case, electrical apparatus proved useful in only 15 per cent.

### 405. Etiology and Treatment of Asthma.

DANIÉLOPOLU (*Bull. et Mém. Soc. Méd. des Hôp. de Bucarest*, No. 10, December, 1924) states that, in spite of the great number of publications on this subject, the etiology of asthma is still obscure. As the result of much study of the "vegetative" nervous system, which plays an important part in the production of asthma, he has come to the conclusion that the "vegetative" nerve tone of an organ may be modified by local intravisceral or extravisceral factors, as also by reflex and general factors. The "local" factor is, he thinks, the most important and is often represented by some local visceral lesion, such as a chronic tuberculous focus with accompanying fibrosis, or again fibrosis may result from a penetrating gunshot wound of the lung. Daniélopou believes that these lesions act in two ways—(a) by irritation of the nerve endings (both sensory and motor) in the lung, and (b) by forming "a local anaphylactic focus." The author claims to have demonstrated that the tuberculous lung is in a condition of "local anaphylaxis," not only for the specific toxins of the tubercle bacilli, but also in respect of certain albumins which have been more or less modified by tissue destruction. There is also a "local focus of anaphylaxis of the tissues without obvious lesion." In such cases the

sensitizing agent is inhaled, and in addition to general sensitization there is a predominating local anaphylaxis, as in hay asthma and in Vidal's case, in which asthma was induced by the odour of sheep. A general factor is represented by a "parasympatheticotonia." The atropine test shows that this condition is far from constant in asthma, but it plays an important part in some cases; for example, it explains the occurrence of asthma in Graves's disease. A reflex factor is present in those cases in which asthmatic attacks are provoked by nasal diseases, or by those of the adnexa or of the appendix. There is also a psychic factor: in certain cases emotion induces an attack. Recent physiological research indicates a derangement of the centrifugal and centripetal nerve fibres of the bronchi. The bronchoconstrictor fibres arise in the dorsal nucleus of the vagus and pass downward to the bronchi by the cardiac and pulmonary branches of that nerve. The broncho-dilator fibres arise from the first four dorsal nerves, and reach the bronchi through the stellate ganglion and its cardiac branches. The sensory (centripetal) fibres form (a) an ascending group which follows the vagus and its branches and (b) a lateral group which traverses the stellate ganglion and the first four dorsal roots to reach the cord. It matters not, according to Daniélopou, what may be the factor which determines an attack, the attack can only occur when there is a predominant parasympathetic reflex circle, which is stimulated by the local factor. The resection of the sympathetic or of the vagus trunks has relieved some patients; this can, he thinks, only be explained by the anatomical details given above. Anaphylaxis does not account for every case of asthma. Asthmatic attacks may be prevented by—(a) lessening the excitability of the intrapulmonary motor terminations or of the parasympathetic system, when involved; calcium chloride and potassium iodide are often very useful; (b) prevention of anaphylaxis, when the asthma is due to this cause, auto-serotherapy, auto-haemotherapy, and protein therapy. In severe cases in otherwise healthy young patients, Daniélopou recommends excision of the cervical sympathetic, avoiding the inferior cervical ganglion and the stellate ganglion, with division of the vertebral nerve, the operation recommended by the author in angina pectoris, but in asthma it should be performed on both sides.

### 406. Enuresis and Spina Bifida Occulta.

MOURIQUAND, CHASSARD, and SÉDALLIAN (*Lyon Méd.*, February 15th, 1925, p. 198) state that German authors have claimed that spina bifida occulta is present in 83 per cent. of cases of enuresis, and that where radiological proof of this deformity is lacking a dysplasia of the spinal cord is present. They describe the case of a boy aged 8 who had always suffered from nocturnal enuresis and diurnal frequency of micturition. The x-ray examination showed a spina bifida occulta, with an oblique gap 1 cm. in width in the arch of the first sacral vertebra. In a girl aged 5, whose enuresis ceased on treatment in hospital, a narrower fissure was detected radiologically in the same vertebra, but since cartilaginous islets may persist in this region until the age of 7 the evidence in this case is held to be less convincing.

## Surgery.

### 407. Femoral Aneurysm cured by Excision.

P. DELBET (*Bull. et Mém. Soc. Nat. de Chir.*, February 14th, 1925, p. 154) records the result of an operation for a large aneurysm of the lower end of the femoral artery in a patient aged 65 years. The aneurysm was very large and showed marked pulsation; it had recently been causing pain in the leg and difficulty in locomotion. The swelling was limited below and did not extend into the calf; above it passed into Hunter's canal. As it seemed likely that the aneurysm would rupture unless treated it was decided to try to excise it. The Wassermann reaction proved to be negative. The operation was exceedingly difficult owing to the fixity of the aneurysm to the surrounding structures, whilst the vein was very adherent to its walls. As it does not appear to be necessary to preserve the vein in these cases, and owing to the difficulties present, it was ligatured and divided. The patient recovered completely. Delbet considers that these large aneurysms are suitable for operation, which gives satisfactory results. In another case where it had been proposed to amputate the leg for a similar condition he excised the aneurysm successfully and cured the patient.

## 408. Treatment of Varicose Veins.

D. FISHER and E. H. MENSING (*Journ. Amer. Med. Assoc.*, March 7th, 1925, p. 728) emphasize the importance of carefully investigating the condition of the deep veins of the leg before removing the superficial ones when these are varicose. They report two cases. The first patient, a man aged 32, was admitted for the removal of varicose veins in both legs. Before the operation the legs were raised so as to remove the blood, then a constriction was applied to the saphenous opening and the leg lowered; even after ten minutes the veins had not filled up again, showing that the deep or perforating veins were thrombosed or in a varicose condition. There was a previous history of typhoid fever, and had operation been performed gangrene of the extremities would probably have resulted. In the second case the patient had had varicose veins removed and gangrene of one leg followed. Subsequent examination showed that both the deep and perforating veins were thrombosed.

## 409. Osseous Metastasis from Breast.

G. T. BEATSON (*Brit. Journ. Surg.*, vol. xii, No. 47, 1925, p. 473) reports a case of osseous metastasis from primary carcinoma of the right mamma. He points out the confirmation given by it to the theory of omolism of metastases through the blood, and that it was shown also that lymphatic infection can take place simultaneously. A woman, aged 55, with carcinoma of both upper quadrants of the right breast, developed extensive metastatic involvement of the skin, glands, pleurae, clavicle, skull, and vertebrae through the lymph stream, and of the long bones of all the limbs and the liver, lungs, and kidneys through the blood stream. Fractures of the right clavicle, the left humerus, and the left femur occurred, and Bence-Jones albumin was present; there was a secondary anaemia and a marked leucocytosis, mainly of polymorphs. Skiagrams showed that the cancerous foci were not more frequent in the tendinous and fascial insertions, and large nodules and masses of tumour tissue were demonstrated in the radii, ulnae, tibiae, and iliac, chiefly in the marrow cavities. The main points of interest were the extensive involvement of the distal bones of the limbs, contrary to the rule that the liability of a bone to metastases is greater the nearer it is to the primary growth; the fracture of the femur in the upper third of the shaft and not where the compact bone is thinner; the fracture of the humerus below the deltoid insertion; the unusual feature of the freedom of the sternum from growth, whereas it frequently becomes involved through the lymphatics; and the scarcity of skin nodules although the osseous spread was very diffuse. The author points out that the dictum that "the spread of cancer is invariably by the lymphatics" needs some modification in view of this case, which confirms the conclusions of Piney that metastatic deposits in bones are due to arterial or capillary embolism.

## 410. Staphylococcal Septicaemia.

CABELLO (*La medicina Ibera*, March 7th, 1925, p. 235), who alludes to the case recently reported by Moya (*Epitome*, January 24th, para. 89), records the case of a man, aged 26, in whom the first symptoms of this condition, consisting in a rapid pulse and a temperature of 103°, developed a few hours after operation for femoral hernia. Examination of the blood showed a leucocytosis of 15,200 and a polymorphonuclear percentage of 78. Death followed two days later, there being no thoracic or abdominal signs other than feeble air entry at both pulmonary bases. At the autopsy the operation wound was filled by sero-purulent exudation containing numerous staphylococci. Cultivation of the blood from the left ventricle showed a pure culture of *Staphylococcus pyogenes aureus*. Apart from slight endarteritis of the femoral artery nothing else abnormal was discovered.

## 411. Spontaneous Gangrene of the Testicle.

A. BUSCHKE (*Deut. med. Woch.*, February 6th, 1925, p. 229) does not consider insidious gangrene of the testicle from an unknown cause or causes to be very rare, and he classifies gangrene and abscess formation of the testicle in three main groups, according as the cause is—(1) acute gonorrhoea, (2) chronic gonorrhoea, or (3) unknown. With regard to the authorities that castration should be performed. He has gradually given up castration, having found that in many cases, notably when the onset of the disease was insidious phlogistic treatment led to recovery and the reabsorption of the necrotic tissues. In other cases he limited operative treatment to aspiration of the associated hydrocele and excision of the testicle, the necrotic elements of which were enabled to escape by elongating. One merit of this conservative treatment is that part of the testicle is retained

and is still able to function. Another advantage of not castrating is concerned with the psychology of the patient, on whom this operation is apt to act as a psychic trauma. The author distinguishes this form of gangrene of the testicle from the one following torsion of its pedicle, and while in some cases the onset of the disease is marked by acute symptoms, there are other cases in which the process is gradual and insidious.

## Therapeutics.

## 412. Dangers of Hydrogen Peroxide Irrigation.

J. S. OIESTAD (*Tidsskrift f. d. Norske Lægeforening*, March 1st, 1925, p. 237) records several cases to emphasize his point that it is unwise to encourage the general public to use indiscriminately hydrogen peroxide as a lotion for the ears and a gargle for the throat. Owing to the rapid generation of gas on contact between hydrogen peroxide and pus, pressure within certain cavities of the head may rise to such a point as to cause loss of consciousness and even death. One of the author's patients had used hydrogen peroxide for a sore throat, with the result that severe earache developed on one side, and when he was examined a couple of hours later the tympanum was still bulging much forward, as the result, no doubt, of the escape of oxygen through the Eustachian tube. Another patient, who suffered from nasal catarrh and the formation of crusts, was recommended irrigations with hydrogen peroxide. The first irrigation was immediately followed by swelling and reddening of the nose. This condition lasted several days, and ulcers, which formed just within the nostrils, left depressed scars. Several other patients complained of burning in the throat with more or less severe dysphagia after using hydrogen peroxide as a gargle. In one of these cases the pain was so violent that the patient screamed incessantly for four hours, and when she was examined next day there was still great swelling with tenderness of the throat, and she could not drink even water. The author suggests that in this case the bubbles of gas had forced their way into the tonsillar crypts and between the tonsils and the palatine arches. In another case hydrogen peroxide was introduced into the ear of a girl, aged 10, whose tympanum was subsequently found to be eroded. Directly after the hydrogen peroxide was introduced into the ear, the girl shrieked with pain and continued to do so incessantly for about twenty-four hours. The author does not mention the strength of the solutions used in his cases.

## 413. Treatment of Anasarca due to Cordic Follure.

A. PISANI (*Chiore e circolazione*, February, 1925, p. 71) records five cases in men aged from 54 to 72 suggesting that the commercial preparation, novarsol, which is a combination of sodium oxymercurechlorophenoxy acetate with dimethylmoniluria, and was first employed as an antisyphilitic drug, is of value in the treatment of anasarca due to the failing heart when other remedies such as digitalis and strophanthus have failed. Even in healthy subjects it has a well marked diuretic action, but this effect is still more pronounced in cases of oedema. Novarsol does not stimulate either the heart or the kidneys, but it has the property of mobilizing the oedema fluid, which it drives into the renal filter, giving rise to a copious flow of urine containing the chlorides and other salts which have intoxicated the system. In patients who previously passed 500 to 600 c.cm. of urine in the twenty-four hours the diuresis is increased four-, five-, or ten-fold, with the result that the oedema disappears and the respiration becomes unembarrassed. A subcutaneous injection of 1 c.cm. every two or three days is sufficient. The author mentions only one contraindication—namely, acute or chronic nephritis, owing to the irritation produced in the kidney by the mercury in the preparation.

## 414. Magnesium Sulphate in Eclampsia.

E. M. LAZARD (*Amer. Journ. Obstet. and Gyn.*, February, 1925, p. 178) gives a preliminary report of encouraging results obtained by intravenous injection of magnesium sulphate in eclamptic patients. He believes that, besides controlling the convulsions by its sedative action on the voluntary muscles, the drug has a detoxicating action due to its promoting urinary secretion and also that it diminishes cerebral oedema. Seventeen cases are reported, of which five were examples of post-partum eclampsia: all the patients were comatose on admission. All the mothers except one recovered, and five of the eleven babies delivered after starting magnesium sulphate treatment were living. The injections invariably controlled the convulsions: the dose found best required one or two repetitions. No evidence of respiratory paralysis was detected. In many of the cases the treatment

was combined with administration of morphine and eliminative measures such as phlebotomy, gastric lavage, and colonic flushing. The magnesium sulphate injections appeared to possess the greater efficacy, and the best results were obtained with the least handling of the patient. B. H. ALTON and G. C. LINCOLN (Ibid., p. 167) deal with intraspinal injections of magnesium sulphate solution. The drug appears to have been first given by this route in eclampsia by Einar in 1907, and has been employed occasionally since this time with varying results. It is remarked that there is an analogy between its action in eclampsia and in strychnine and tetanic convulsions. The present authors have injected intrathecally in the lumbar region doses corresponding to 1 c.cm. of 25 per cent. solution to each 25 lb. of body weight. Four patients were given this treatment after the usual eliminative measures had failed. After each injection the convulsions ceased at once, and the minimum time in which the eclamptic convulsions were controlled was eighteen hours. Two of the patients recovered. Animal experiments have shown that overdose leads to respiratory paralysis, to which intravenous injections of 10 c.cm. of 25 per cent. calcium chloride act as an antidote.

## Dermatology.

### 415. Erythroedema.

J. BUTLER (*Arch. Derm. and Syph.*, February, 1925, p. 166) records a case of erythroedema or "pink disease." He considers that it is often wrongly regarded as acrodynia and that the cutaneous manifestations, which are among the first to appear and the last to disappear, are pathognomonic of a definite clinical entity occurring in infants and young children. The child becomes extremely irritable, depressed, and drowsy; it lies face downwards with the head buried in the pillow. Anorexia is associated with profuse sweatings, photophobia, diminished reflexes, and paraesthesia of the extremities. The skin lesions consist of a miliary rash on the body and a typically diagnostic cyanotic red, swollen, scaling condition of the hands and feet. This last is the most constant symptom, commencing about the second week and continuing throughout the disease. Commencing between the ages of 3 months and 7 years, the illness is marked by exacerbations and remissions of varying duration. The prognosis is good, but about 5 per cent. of the patients die, generally from pneumonia. Treatment is symptomatic and forced feeding may be decided. A carbolic calamine lotion for the skin and ultra-violet light therapy of the hands and feet afforded relief. In some patients improvement has followed removal of the tonsils and adenoids and treatment with a vaccine from diplococci found in the lymphatic glands.

### 416. Haemochromatosis.

S. WILSON and F. A. WEISER (*Journ. Amer. Med. Assoc.*, March 14th, 1925, p. 800) report a case of haemochromatosis occurring in a man, aged 37, the diagnosis being made during life and confirmed by necropsy. The prominent signs in this case were a diffuse greyish-blue pigmentation of the skin, with small elevated brownish patches. This pigmentation was marked over the face, neck, and upper part of the chest, and the skin was dry and scaly. Intracellular haemosiderin granules were demonstrated in the skin and in the urinary sediment. The liver was enlarged, and there were hyperglycaemia, glycosuria, acidosis, and cachexia. The onset was rather sudden, the first symptom being a feeling of fullness in the upper abdomen, not accompanied by nausea or vomiting, but soon followed by progressive weakness and loss of weight, together with dryness of the skin. The blood count showed diminution of haemoglobin and red and white cells; the differential count was normal. The blood platelet count was 49,600; reticulated red cells were found in the proportion of 1 to 300, and the fragility test showed—complete, 0.325, and partial, 0.475. The patient subsequently died in a condition of diabetic coma. The authors discuss the diagnosis of the condition, with special reference to the exclusion of cirrhosis of the liver, arsenical poisoning, Addison's disease, and syphilis. They have been able to find only eighty-four cases previously reported in the literature.

### 417. Auto-serotherapy in Dermatology.

P. CASTELLINO (*Rif. Med.*, February 2nd, 1925, p. 57) records 22 cases of skin diseases treated with injection of serum or blood taken from the patient: 14 were cases of chronic eczema, 4 of prurigo, 1 of pemphigus, 1 of ichthyosis, and 2 of leprosy. The best results were obtained in the eczema cases, and in these cases serum was found to be better than blood. Of the 14 eczema cases only 3 showed no good result; the rest were either completely cured or very much improved. The ichthyosis case was improved by haemotherapy; in the

pomphigus case serotherapy gave some benefit. The leprosy cases were not improved at all. The author suggests that the good results are due to an effect on the lymphatic system. The dose of serum given varied from 3 to 7 c.cm., and of blood from 5 to 15 c.cm.; they were injected intramuscularly. The age of the patients varied from 9 to 69 years.

### 418. Treatment of Chronic Skin Diseases.

A. HOLLÄNDER (*Deut. med. Woch.*, March 13th, 1925, p. 439) recommends the prolonged administration of suprarenal extract for obstinate and relapsing weeping eczema and for all the erythrodermias, notably Hebra's pityriasis rubra. He treats with subcutaneous injections, after the month. A few hours after there is a diminution of the previously unbearable itching and sense of heat in the affected area. After two or more injections the moisture and associated urticaria abate appreciably, and when this treatment is supplemented by such mild remedies as zinc ointment cases which have hitherto proved intractable terminate in complete recovery. The technique of the procedure is as follows: Every day, for four or five days, a subcutaneous injection of 1 c.cm. of a 1 in 1,000 solution of adrenaline hydrochloride is given. Then, for the next six to eight weeks, adrenaline is taken by the mouth every two hours, a teaspoonful of Unna's syrup (10 c.cm. of a 1 in 1,000 solution of adrenaline hydrochloride to 100 c.cm. of syrup of orange peel) being given. This treatment, Holländer adds, can be continued for weeks and even months, for eight teaspoonfuls of this syrup contain only 4 mg. of suprarenin, and this is less than the total quantity excreted under normal conditions by the suprarenals every day. The author suggests that the beneficial effect of adrenaline in certain skin diseases depends on its action on the capillaries, and he insists that it is only by giving the extract continuously over a long period that a permanent cure can be expected.

## Obstetrics and Gynaecology.

### 419. Ovarian Activity and Vasomotor Symptoms.

A. BÉCLÈRE (*La Gynécologie*, January, 1925, p. 55) discusses the connexion between ovarian activity on the one hand and menstruation and the vasomotor symptoms of the menopause on the other. Among 700 women whose ovaries had been exposed to x-ray treatment, in 34 the ensuing menopause proved to be temporary only, lasting in the majority of cases from three to seven months. The return of menstruation was preceded invariably by disappearance of the "flushings" which had accompanied the temporary amenorrhoea. The conclusion is drawn that the vasomotor phenomena of the menopause are not due to retention of substances eliminated normally by menstruation. The persistence of "flushings" is incompatible with a reawakening of ovarian activity—a point for which diagnostic importance is claimed. When uterine haemorrhages recur after the natural or an artificially induced menopause, the persistence of vasomotor symptoms indicates that such haemorrhages are probably not menstrual but have some other origin. Thus in three patients who had uterine bleeding after a period of amenorrhoea following x-ray treatment, and in whom well marked "flushings" persisted, submucous polypi were found.

### 420. Lumbar Puncture before Podalic Extraction.

ACCORDING to R. COSTA (*Riv. d'Ostet. e Ginecol. Prat.*, February, 1925, p. 65), lumbar puncture of the foetal spinal canal as a preliminary to extraction in certain breech deliveries has the advantages that—(1) the whole cerebro-spinal axis, including the respiratory and other bulbar centres, is thereby exposed to diminished pressure during delivery; (2) the biparietal diameter may undergo a reduction of as much as 0.5 cm. during passage through the pelvis; (3) the degree of compression of the antero-posterior diameter of the foetal head with lengthening of the vertical diameter is diminished, so that the risk of tearing the tentorium cerebelli becomes less. The procedure has been employed by Costa in ten cases, in eight of which the infant survived, and in three cases by other Italian accoucheurs, with subsequent live-birth. Costa thinks it is indicated whenever extraction of the after-coming head is necessary, whether the dystocia arises in the soft or in the bony maternal parts. The infant's back being flexed, a needle is introduced horizontally between the fourth and fifth lumbar vertebrae, the position of the spine of the former being given by the line joining the two iliac crests. The needle is left in position during extraction of the head, and gives issue to cerebro-spinal fluid under considerable pressure during the passage of the head through the pelvis.

421.

**Pelvic Pain.**

DISCUSSING the place of 'sympathectomy' in gynaecological treatment G. COTTE (*La Presse Médicale*, January 24th, 1925, p. 98) recalls the two operations by which in 1899 Jaboulay divided the connexions of the presacral sympathetic cord with the pelvic plexus. Both patients were relieved of severe pelvic neuralgia and vaginismus. The visceral nerve fibres in the sheath of the internal iliac artery have been divided by Leriche and others in three cases of severe neuralgia and one of kraurosis vulvae. Cotte has performed hypogastric sympathectomy in five cases, of which two date respectively ten and fourteen years back. The first of these patients, a single woman, aged 28, had dysmenorrhoea unimproved by other treatments: after a bilateral operation the pain at the menses ceased, but there was persistent general nervousness. Relief was equally lasting in the second patient, a woman, aged 23, complaining of dyspareunia and exhibiting hyperaesthesia in the region of the utero-sacral ligaments. In this case chronic cellulitis in the parametria was demonstrated at operation. Cotte concludes that operations of this sort are suitable for intractable dysmenorrhoea, pelvic neuralgia, and pelvic hypoaesthesia. He is inclined to prefer to Leriche's operation division of the presacral nerve or its branches, combined in certain cases with partial or complete ovarian resection. He has had encouraging results recently. The abdominal route is considered the better, permitting detection of any morbid organic conditions present.

422. M. H. VIOLET (*Lyon Médical*, January 18th, 1925, p. 61)

states that a certain number of cases of intractable dysmenorrhoea are due to pressure on the nerves of the uterus by inflammatory nodules or massive inflammations in the parametrium which may be detected by rectal examination. In four instances he has treated these patients by effecting a dissociation of the cellular tissue in the base of the broad ligaments. The posterior surface is incised parallel to the ureter, which is separated, and the cellular tissue of the parametrium is torn by means of closed scissors. The results have been good and in one case relief has lasted ten years.

423.

**Myomata and Radiotherapy.**

R. CROUSSE (*Gynéc. et Obstét.*, 1925, xl, 2, p. 135) describes the case of a 3-parous woman, aged 56, who had a myomatous uterus extending to five fingerbreadths above the pubis. The tumour was thought to be interstitial, and was treated by twelve x-ray applications. The haemorrhage decreased for a short time, but reappeared in greater amount. Eighteen months after the x-ray treatment the uterus was of undiminished size and the sound penetrated 5 inches. The myoma was still thought to be interstitial; it was removed by operation, and found to be spherical, sessile, and submucous. Crousse believes that similar errors are not uncommon, and suggests that routine preliminary dilatation of the cervix and exploration of the uterus would negate the use of radiotherapy, which is admitted to be unjustified in cases of submucous myoma. Such a dilatation, Crousse points out, adds no complication to radium treatment, and in contemplated x-ray treatment may allow the extirpation of small myomata.

**Pathology.**

424.

**Early Diagnosis of Poliomyelitis.**

E. C. ROSENOW (*Journ. Amer. Med. Assoc.*, February 7th, 1925, p. 429) describes a specific precipitin reaction in epidemic poliomyelitis obtained by pouring gently a clarified extract of naso-pharyngeal swabbings in sodium chloride solution on to the surface of antistreptococcal horse serum used in the treatment of the disease. In positive cases, he reports, a cloud forms at the line of contact. Two readings are required—the first after incubation for two hours and the second after the tubes have been in the refrigerator overnight. These readings are taken in a darkened room by transmitted light, the tubes being viewed against a black background. Normal horse serum and other immune serums were used as controls. A large number of cases of the disease and of contacts were tested; several control tests were made upon persons suffering from miscellaneous diseases and upon normal persons both inside and outside the epidemic zones. Rosenow found the reaction positive at the onset of the disease before paralysis had developed, and consequently he considers the test of value in early diagnosis, thus enabling serum treatment to be started. Since the reaction usually became negative in from two to three weeks the test should, he adds, be of value in determining quarantine. Similar results obtained in cases of encephalitis and scarlet fever suggested that the corresponding tests might be of value in other diseases.

**The Action of Insulin.**

V. LAUFBERGER (*Klin. Woch.*, January 25th, 1925, p. 151) remarks that there is still great divergence of opinion on the essential nature of the action of insulin. Most investigators appear to think that it increases carbohydrate excretion, but Laufberger's experiments on rabbits and frogs do not confirm this view. He believes that insulin regulates indirectly the carbohydrate exchange; this control is not exercised, apparently on particular organs, but upon all the tissues of the animal. He is of opinion that insulin has no direct influence on the oxidation of carbohydrates, and considers it more probable that it assists in the building up of the carbohydrate reserve rather than modifying or arresting its exhaustion.

426. **Cultivation of the Bacillus of Soft Chancre.**

As isolation of Ducrey's bacillus is often difficult, J. HADAROT-SALA (*C. R. Soc. de Biologie*, February 27th, 1925, p. 498) gives an account of the method with two media which has proved successful in his hands. The fluid medium consists of a mixture of nutrient broth with Beaudouin's egg medium in the proportion of 1 part to 4; 5 per cent. glycerin is added to the broth—presumably after mixing. The solid medium is made by substituting nutrient agar for the nutrient broth; the melted agar is added aseptically to the egg medium, and tubing is performed without further sterilization. Both of these media are suitable for the growth of meningococci, gonococci, and pneumococci, as well as for the bacillus of soft chancre. For isolation of this bacillus from the tissues some of the fluid from a closed chancre is taken and inoculated on to one or two plates of the solid medium. The resulting colonies of the bacillus are rod-like, transparent, and of a pink mother-of-pearl colour. Subcultures give an abundant, confluent growth in twelve hours, remaining alive at room temperature for more than a month. The identity of the bacillus may be proved, not only by the fact that it is Gram-negative and tends to occur in groups which are difficult to dissociate, but also by agglutination and by the intradermal test on patients who are actually suffering, or who have suffered, from the disease. For preparing a vaccine it is recommended that the bacillus be grown for ten to fifteen days in the fluid medium, in which it gives rise to a light turbidity and a heavy viscous deposit; it is then filtered through an L3 candle, and heated to 60°C. for one hour. The results obtained by vaccine treatment, giving injections every day, are reported as being distinctly favourable.

427.

**Gastric Secretion.**

R. K. S. LIM, A. C. IYI, and J. E. MCCARTHY (*Quart. Jour. Exper. Physiol.*, March, 1925, p. 13), as the result of experimental investigations in men and dogs, have reached the following conclusions with regard to the flow of gastric juice. They find that there is a "basal" or fasting secretion, contrary to the belief of Beaumont and Pavlov. A flow of gastric juice was caused by mechanical stimulation, and was unaffected by removal of the vagi. Increase in intragastric pressure by air or water similarly stimulated secretion, as did local mechanical stimulation. It is suggested that this is due to direct action on the gland cells or to vagal or local reflexes. Certain chemical substances, such as raw meat juices, beta-naphthol, histamine, sodium chloride solution, 50 per cent. glucose, and Liebig's extract, in small quantities, stimulated the flow of juice, whereas starch, cane sugar, and fat were without effect. Water only acted as a stimulant when the viscous was distended by it. Chemical stimulation still occurred when the nerve supply had been severed. Water was absorbed from the stomach of anaesthetized animals if left there for half an hour to an hour. Atropine abolished secretion and annulled mechanical or chemical stimuli. Fat in the intestine inhibited gastric secretion, but fat in the stomach only had a very slight inhibiting influence. All stimuli seemed to act primarily by increasing the supply of blood to the glands; no evidence of the existence of a hormone was detected. The authors found in some cases that gastric secretion was induced by the sight or odour of food after the cortex of the brain had been removed. They also found that gastric juice was secreted after a latent period of from one to three hours, when a mixed meal was introduced directly into the intestine. They call this the "intestinal phase" of gastric digestion and ascribe it to the action of poptones, amines, and amino-acids, since it was not produced by such raw foods as meat, carbohydrates, and neutral fats. Water in the intestine was found to stimulate the gastric secretion, and a non-absorbable substance, such as 0.5 per cent. solution of saponin, was found to stimulate gastric secretion through changes in surface tension. The authors believe that their observations definitely disprove the elaboration of a specific hormone by the pyloric mucous membrane.

# EPIHOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 428. Acute Rheumatic Disease of the Heart.

W. S. THAYER (*Bull. Johns Hopkins Hosp.*, February, 1925, p. 99) analyses a series of 25 cases (17 males, 8 females) of acute or subacute endocarditis which appeared to be of indisputably pure rheumatic origin, without any demonstrable complicating bacterial septicaemia. As many as 19 of the cases occurred in the first two decades of life, 22 in the first three. Pre-existing valvular disease was the rule. While the etiological element was not apparent, the sequence of the disease on acute tonsillar or naso-pharyngeal infections was striking. Every patient had had arthritis during the attack or previously, but in a surprisingly large proportion the arthritic symptoms were slight, the disease being one of the heart rather than of the joints. Especially significant was the presence of unaccountably persistent fever in association with chorea or mild atypical arthritis, and a pronounced leucocytosis. Embolic phenomena were absent. Albuminuria was the rule, but no red blood corpuscles were observed in the urinary sediment. These 25 cases of rheumatic heart disease were, almost without exception, a true pancarditis: endocarditis, myocarditis, and pericarditis occurred with almost equal frequency. The one characteristic lesion appeared to be the perivascular Aschoff bodies, which were found not only in the heart muscle, but in the affected pericardium, in the auricular wall, and even occasionally in the affected valves. The myocardial and pericardial changes appeared to be the gravest features of acute rheumatic heart disease, and led, of themselves, to a fatal issue while the endocarditis was yet in an early stage. The endocarditis affected the mitral and aortic valves in the great majority of cases, especially the former, but the tricuspid valve was implicated in 11 cases. Bacteriological studies were negative in every case in which they were made.

### 429. Haemophilic Pseudo-coxalgia.

M. CAMURATI (*Bull. delle Sci. Med.*, January-February, 1925, p. 94) reports a case of arthritis of the hip in a boy, aged 8½, who had been brought to the Rizzoli Orthopaedic Institute at Bologna for pain in the left hip and limping following a slight injury a month previously. There had been no previous illnesses, but ever since the first months of life the boy had shown a tendency to bleeding after the slightest injury. The grandmother on the father's side had probably suffered from haemophilia. Abduction and internal rotation movements of the boy's hip were very limited: a radiogram showed slight atrophy of the upper extremity of the left femur and irregularity of the epiphyseal cartilage. The movements became completely normal again after a few days' rest. Five months later the boy had a slight injury to the right hip followed by pain and limping, a radiogram showing the same appearances as on the previous occasion. The von Pirquet and Wassermann reactions were negative, so that tuberculous and syphilitic hip disease could be excluded. In support of the diagnosis of haemophilic arthritis, of which 18 cases had occurred at the Rizzoli Institute, including 7 examples of polyarthritis, were the following haematological findings: increased coagulation time—eleven minutes more than the control; increased bleeding time—fifty minutes more than the control; much diminished capillary resistance ranging from 8 to 14 cm. Hg.

### 430. Prognosis in Scarlatinal Nephritis.

H. HANSBERG (*Acta Med. Scand.*, February 12th, 1925, p. 570) finds that the prognostic significance attached by various authorities to scarlatinal nephritis differs considerably; he has therefore investigated the condition of the kidneys of such patients from one to ten years after discharge from the Blegdam fever hospital in Copenhagen, where they had been treated for scarlatina complicated by nephritis. In the ten-year period, 1911-20, there were 14,339 cases of scarlatina treated in this hospital, which admitted 75 per cent. of all the cases of scarlatina notified in Copenhagen. Among these patients there were 612 who suffered from haemorrhagic nephritis, which in several cases proved fatal in the acute stage of the disease. Of the surviving 588 as many as 284 were re-examined from one to ten years after discharge, the blood pressure being measured, the heart auscultated, and the urine examined by the ordinary tests for

with a view to determining the presence or absence of orthostatic albuminuria. Of the 284 ex-patients, 23 were found to be suffering from albuminuria of a purely orthostatic character, 1 was suffering from chronic nephritis with characteristics distinguishing it from that of scarlatina, 259 showed no evidence of renal disease, and only 1 suffered from albuminuria which still persisted five years after the onset of the scarlatinal nephritis. The author concludes that the damage inflicted by scarlet fever on the kidneys is almost invariably only temporary, and that the frequency of orthostatic albuminuria is not greater among persons who have suffered from scarlatinal nephritis than it is among other persons.

### 431. Renal Sequelae of Bismuth Administration.

W. ENGELHARDT (*Derm. Woch.*, February 28th, 1925, p. 338) records a large number of cases of albuminuria, accompanied sometimes by the presence of epithelial, granular, or hyaline casts, or even haematuria, following bismuth administration, intravenously or intramuscularly, or in a few instances orally. He thinks it possible that such impurities in bismuth preparations as arsenic, tellurium, and phosphorus are the cause of the kidney lesions; or that some lesions may be syphilitic, the specific action of bismuth stimulating the renal cells and producing transient albuminuria. It is not yet certain whether chemically pure bismuth can damage the renal cells in healthy animals and human subjects. The frequency of albuminuria varies greatly: Escher detected it in 15 per cent. of his cases, Richter in 8 per cent., while Rosenberg and Perdiowitz found only 1 per cent. and that of a mild type. R. Neucendorff has reported that in 43 patients treated with "bismogenol" there was severe kidney damage with granular casts and erythrocytes and considerable permanent functional derangement as shown by impairment of the concentration capacity. Von Folke states that albuminuria preceded any renal degeneration, which he regards as evidence of permanent injury; F. Dietel, on the other hand, does not consider the presence of epithelium in the urine as a serious portend. A. Nadel had one undoubted case of acute nephritis with oedema following two intramuscular injections of a 12 per cent. emulsion of bismuth iodo-oxygallate. Levaditi first employed intravenous injections of liquor bismuthi et ammonii citratis (9 per cent. bismuth citrate): in one case there was definite diuresis, and 3 per cent. albuminuria, with hyaline and granular casts, after one injection. Spack administered bismuth in a case of chronic nephritis, with the result that a serious aggravation of the nephritis occurred and the albumin was increased to 17 per cent. Blum, Kollert, Strasser, and Rosner have administered trepol to 39 patients. In one case it was followed by very severe albuminuria (with epithelial, granular, and hyaline casts).

### 432. Sudden Death after Pleural Puncture.

In reviewing the literature of sudden death after pleural puncture M. LÉON-KINDBERG (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 5th, 1925, p. 150) gives prominence to Cordier's grouping of them into three types—the epileptiform, the hemiplegic, and the syncopal. The author is in agreement with Cordier's theory of a reflex of pleural origin, and is against Brauer's theory of gas embolism. The case is described of a male, aged 23 years, with tuberculosis of the upper left lobe, the right lung appearing to be healthy. Artificial pneumothorax was induced in September, 1923, subsequent to which there was a fall in temperature and considerable general improvement. When the author first saw the patient in January, 1924, he found the man's general condition satisfactory, he felt well, his appetite was good, and he was putting on weight. The local signs were unfavourable, collapse of the lower lobe only had been achieved, the upper lobe being adherent to the parietal pleura. Moist sounds and pectoriloquy were heard below the clavicle and in the subspineous fossa on the left side. A few fine moist sounds were heard over the right lung. The sputum contained many tubercle bacilli. The patient had apparently benefited from the partial pneumothorax, and it was decided to continue the "refills," fortnightly at first, and later once a month. The combination of improvement in general health with persistence of unfavourable local signs continued. At a periodic "refill" on December 1st, 1924, the needle had just been introduced into the pleural cavity and the manometric reading of -4 noted when a look of anguish appeared on the patient's face, there was right facial paralysis, conjugate deviation of the eyes, enlarged fixed pupils, and right-sided hemiplegia. Epileptiform convulsions of the affected

side developed, coma followed, and death supervened in a quarter of an hour in spite of energetic stimulation. The autopsy showed extensive tuberculous infiltration, with cavity formation, of the left upper lobe with a few small tubercles in the lower lobe and on the right side. The left upper lobe was completely adherent to the parietal pleura. The brain showed no trace of haemorrhage, softening, or embolus. There was nothing found in the other organs to account for the sudden death. The author cites another case where on introducing the needle for a periodic "respi," the manometric reading in this case being positive, right-sided hemiplegia, coma, and convulsions supervened. But in a moment these disappeared and two hours later the patient seemed none the worse for his attack. The author thinks it impossible to explain these cases except on the theory that they are due to a reflex of pleural origin.

### 433. Diabetes Mellitus and Pressure on the Pancreas.

J. COTTON (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, March 10th, 1925, p. 184) points out the need of trying to remove the cause of the pancreatic disease in diabetes. He thinks that in many cases careful clinical and radiological examination will lead to the discovery of this cause and to its treatment by appropriate surgical, dietetic, or postural measures. Cotton in 1905 treated a boy suffering from glycosuria who, having heard of the benefits of water drinking, decided to drink a litre of water every evening. The resultant polyuria alarmed his family, and the urine was found to contain 8 per cent. of sugar. In spite of rigorous dieting 5 per cent. of sugar persisted. The boy discontinued his evening water drinking and in fifteen days the glycosuria disappeared. It was found that he always slept on his back. This experience led Cotton in subsequent cases to examine carefully the position of the patients' stomachs when lying in bed. He found that when the patients maintained lateral instead of dorsal decubitus they improved. In 1919 he examined three cases under x rays and each case showed similar relations of the stomach, duodenum, and vertebral column. The patient's condition improved after change of decubitus. A woman, aged 60, had had diabetes for sixteen years and had been confined to bed for three months. In spite of very strict dieting she was emaciated and had ulceration of the lower extremities with 7 per cent. glycosuria. The patient was instructed to lie on her side, sodium phosphate was given each morning, and carbohydrates were added to the diet. The glycosuria diminished and the ulcers healed. During the last eighteen months there had been no glycosuria though the patient was eating ordinary food. Skiagraphs showed that the stomach crossed an unduly prominent lumbar vertebra and that the duodenum again crossed the spinal column at a lower level behind the stomach. It was obvious that the pancreas was subjected to pressure between the stomach, duodenum, and vertebra: this pressure would be increased when the stomach was full. In some cases the duodenum was bound down by an ulcer and secondary adhesions. In these cases and in several others there were symptoms of cholecystitis which was relieved by daily doses of sodium phosphate before breakfast. Cotton suggests that diabetes occurring during pregnancy may also be due to intra-abdominal pressure.

### 434. Artificial Pneumothorax in Pulmonary Tuberculosis.

F. LOUP and L. ZOPPINI (*Schweiz. med. Woch.*, March 5th, 1925, p. 206) record the results of artificial pneumothorax treatment which they prescribed only in twenty-five out of several hundred cases of tuberculosis treated in Geneva. In 45 per cent. the results were good, as shown by a gain of weight, disappearance of tubercle bacilli from the sputum and even of the sputum itself, improvement in the stethoscopic signs, and return to a normal temperature. In 23 per cent. the results were mediocre, the improvement achieved not being permanent. In the remaining 31 per cent. no benefits could be claimed. It was significant that all the patients who derived lasting benefit from this treatment measure were young, and the author considers it a most valuable measure for young patients with progressive unilateral lesions. The earlier it is adopted in such cases, the better the prognosis. In the course of about 400 injections of gas, two accidents were observed. The first was transitory syncope which may have been provoked by mental influences. The second was gas embolism, from which the patient recovered after three days, during part of which there were characteristic signs as amblyopia and partial loss of the fact that a large pneumothorax had already been created, having wounded the lung. The radioscopic evidence suggested that an apical adhesion had given way, the lung being wounded in the process, and torn blood vessels being invaded by a little gas.

## Surgery.

435.

### Solitary Renal Cyst.

X. DELORÉ and P. MALLET-GUY (*Lyon Chir.*, January-February, 1925, p. 3) describe a somewhat unusual case of a large solitary serous cyst of the kidney removed by partial nephrectomy; only about 100 cases of this kind appear to have been recorded. The patient was a woman, aged 49, who for several years had noticed a movable tumour in the right iliac fossa. The swelling varied in size, was freely mobile, and about the size of an orange. Laparotomy showed that it was a cystic tumour arising from the lower pole of the kidney; it was removed with the surrounding area of renal tissue. The tumour appeared to arise in connexion with the lowermost pyramid at the renal pelvis. The cyst contained a fluid resembling urine, and appeared, morphologically, somewhat similar to a hydronephrosis. This was also supported by the variations in size of the swelling noted before operation. The authors note that in these cases ovarian cyst, mobile kidney, and hydronephrosis have to be excluded. If the diagnosis is uncertain laparotomy is indicated; a lumbar incision can be made afterwards if necessary. In this case the tumour was satisfactorily dealt with by the abdominal route, and this appears easier in large swellings. Partial nephrectomy or enucleation of the cyst is preferable in the absence of infection; total nephrectomy appears to have been more often practised in the past for this condition. The patient made a satisfactory recovery.

436.

### Rupture of the Rectus Muscle.

A. G. J. HERMANS (*Nederl. Tijdschr. v. Geneesk.*, January 31st, 1925, p. 467) remarks that the symptoms of rupture of the rectus muscle vary considerably. In typical cases the onset is characterized by a stabbing pain which is localized in the abdomen. After lasting for some time the pain gradually diminishes and only reappears when the affected muscle is stretched. The haematoma may then appear as a swelling of greater or lesser extent and tender on pressure. When the rupture is "intracapsular" the haemorrhage remains confined to the sheath of the rectus and is limited in a horizontal direction by the insertions tendinae. The overlying skin at first is unaffected. The subsequent course varies in different cases. Small effusions of blood are readily absorbed as a rule. According to Hermans, complaints by patients of abdominal pain with a chronic cough are not infrequently due to rupture of the rectus abdominis. In large extravasations of blood there is more likelihood of infection and abscess formation, especially in infections due to *B. typhi* or *B. coli*. Abscesses so formed may disappear spontaneously, leaving only a thickening of the connective tissue, or rupture externally or internally into the peritoneal cavity. In rare cases ossification may supervene, giving rise to myositis ossificans. Treatment may be conservative, relying on the spontaneous absorption of the extravasated blood, or operative. The advantage of incising the skin and anterior wall of the rectus sheath with removal of the blood clot is the more rapid recovery with less chance of complications such as abscess formation, ossification, and ventral hernia. Hermans's patient was a woman, aged 50, in whom a diagnosis of torsion of an ovarian cyst was made. Laparotomy was performed, when an extensive haematoma was found in the right rectus, as well as a large myomatous uterus. It was probable that a chronic cough was partly responsible for the rupture of the muscle in this case. Recovery followed.

### 437. The After-history of Operations for Gall Stones.

P. SEULBERGER (*Deut. Zeit. f. Chir.*, February, 1925, p. 1) states that from 1912 to 1920, 304 patients were operated on for gall stones in the surgical clinic of Göttingen University. In 217 the subsequent history could be investigated: 11 had died, death in two cases being due to carcinoma of the rectum, in one to mammary cancer, in two to peritonitis apparently not connected with gall stones, in one to pulmonary tuberculosis, and in only one to cholelithiasis. In 4 cases the cause of death was not given. The survivors were placed in three groups—namely, (1) 110 patients who had no further trouble after the operation; (2) 70 patients who complained of pain for a varying period after the operation, but subsequently made a complete recovery; (3) 37 patients who never obtained complete relief from their symptoms. In a certain number of cases information was available as to the patients' previous diseases. Five patients in the first group, three in the second, and one in the third had had typhoid fever from eight months to ten years or more before their attacks of cholelithiasis. There were no essential differences in the three groups as regards sex, previous illnesses, or the influence of pregnancy to account for the different results.

of the operation. Secondary operations were performed in 20 cases, or 9 per cent. The causes of recurrence of symptoms were (a) overlooked stones, (b) adhesions, (c) nervous disturbances, (d) dilated remnants of the gall bladder or cystic duct, (e) post-operative hernias or defects in the scars, (f) chronic pancreatitis. Many who complained of pain had an excess or deficiency of acidity in the gastric juice.

#### 428. Disease of the Tibial Tubercle.

M. M. POMERANZ (*Amer. Journ. Surg.*, February, 1925, p. 17) reports a series of seventeen cases demonstrating lesions of the tibial tubercle of the Osgood-Schlatter type. Most cases occur in patients aged 10 to 15, and usually in males. The commonest symptom is pain over the patella tendon and pretilial tubercle, which may develop some time after an injury. Limitation of extension of the leg is usually present, but flexion is rarely affected. Peritubercular swelling is common, and local pretilial swelling and tenderness are always present. The x-ray picture varies; it may show the apophysis incompletely united to the shaft of the tibia, but in old lesions there is a dense reactive sclerosis. The type of case varies according to the severity of the trauma—from simple strains or avulsions of the peritubercle to complete avulsion of the tubercle of the tibia with fragmentation of this process. The condition is usually readily recognized, but has to be diagnosed from sarcoma of the tibia, tuberculous arthritis, syphilis, and osteomyelitis. As a rule the history, together with a careful clinical and x-ray examination, is sufficient to furnish a reliable diagnosis. The cases are usually traumatic, but two of the inflammatory type are recorded.

#### 439. Haemorrhage after Tonsillar Operations.

W. SMITAL (*Zentralbl. f. Chir.*, February 21st, 1925, p. 408) remarks that it is generally admitted that no certain method of arresting haemorrhage after enucleation of the tonsils has yet been devised. As the result of experimental researches on the cadaver he has therefore employed the following technique in three cases with satisfactory results. The palatine arch was divided at the upper commissure of the facial pillars with a sharp bistoury under local anaesthesia and the upper pole of the tonsil exposed with a raspatory. The capsule was then peeled off until the lower pole was reached, when a pedicle about 1 cm. in width was left, in which was the tonsillar artery. The tonsil was then drawn forward with vulsellum forceps and the pedicle was stretched and seized close to the tonsil with Péan's forceps. The tonsil was excised and the pedicle transfixed by a needle armed with silk in a long curved needle-holder; or the pedicle may be crushed in the jaws of the artery forceps and afterwards twisted two or three times. In some cases the artery enters the tonsil at the upper part and is not included in the pedicle; if a bleeding point is seen it should be seized in Péan's forceps and compressed for a few minutes. When the forceps are taken off all bleeding will usually have ceased. If haemorrhage recurs, traction should be applied to the pedicle in order to bring the bleeding point into view, when it should be secured with another pair of Péan's forceps. Smital adds that in some cases deep sutures to obliterate the site of the tonsil may be required, but in such cases manipulative dexterity and practice in the use of the forehead mirror are necessary.

#### 440. Treatment of Trigeminal Neuralgia.

P. DESCOMPS (*Bull. et Mém. Soc. Nat. de Chir.*, March 21st, 1925, p. 327) reports a case of retro-Gasserian neurotomy of the fifth nerve for trigeminal neuralgia in a married woman, aged 39. The pain had started about fifteen months previously, and affected the inferior maxillary division on the right side of the face, severe crises spreading to the superior maxillary division and the temporal region. After unsuccessful attempts to relieve the pain by injections of alcohol into the superior and inferior maxillary divisions, it was decided to operate under general anaesthesia. The skull was trephined in the right temporal region and the dura mater separated from the base of the skull, the brain being held up by a retractor. Haemorrhage was not very troublesome, and the maxillary divisions of the fifth nerve were fairly easily identified. The root of the ganglion was then defined, and after careful separation on a strabismus hook was divided; during these manipulations the motor root was not seen. The operation resulted in complete anaesthesia in the region supplied by the fifth nerve and entire absence of pain. There was no paralysis of the muscles of mastication and only slight facial paralysis for a few days. Descomps adds that the best method of finding the ganglion appears to be to identify first the superior and inferior maxillary divisions and trace them backwards. The roots of the ganglion are then found and the division performed.

#### 441. Textbook Treatment of Dislocation of the Jaw.

A. KOREN (*Tidsskrift f. d. Norske Lægef.*, March 15th, 1925, p. 293) questions the accuracy of the statement in textbooks that when the lower jaw slips back into place, after having been dislocated, it often does so with a click, so that the teeth snap together, endangering the thumbs of the operator. Protection of the thumbs with metal forclips is accordingly advised, or keeping the thumbs beyond the range of the jaws. A preliminary injection of morphine or of a local anaesthetic, such as novocain, is also recommended in order to relax the muscles concerned. Koren records two cases, both patients being recruits, one of whom had dislocated his jaw while yawning. In both cases the dislocations were easily reduced by the conventional manoeuvre, the bone slipping back into its normal position without any click, and the teeth failing to snap in the approved textbook manner. Koren invited his colleagues to relate their own experiences in this matter, and J. M. HEIDENREICH (*ibid.*, April 1st, 1925, p. 356) records three cases, in none of which did he experience any difficulty in saving his thumbs from the hypothetical snapping of the jaws, the bone falling back into place slowly and without a click. C. WINGARD (*ibid.*) also records a case in which the thumbs of the operator escaped injury.

#### 442. Uræmia and Prostatectomy.

H. OLIVECRONA (*Acta Chir. Scand.*, January 21st, 1925, p. 472) gives reasons for believing that the diagnosis of uræmia in many cases of death supervening on prostatectomy is wrong. Prostatectomy deaths occur from twenty-four to forty-eight hours after the operation, with no other sign of uræmia than oliguria or anuria; these, however, may be produced by other causes, such as severe haemorrhage and shock. Olivecrona adds that true post-operative uræmia takes several days to prove fatal, and that the clinical picture of prostatectomy symptoms and death is fairly well defined. In the evening of the day of the operation the patient is somewhat pale and cyanosed; the skin is cold, and there is nausea with, perhaps, vomiting. As much as 7 to 10 ounces of urine may be passed if the patient had been given a pint or two of fluid subcutaneously immediately before the operation; but next day there is practically complete suppression of urine, the pulse is 110 to 120 and very small, and the patient is very cyanosed and bathed in a cold sweat. He is restless and vomits at once whatever he drinks. Death occurs on the second or, at the latest, on the third day, in spite of the administration of diuretics, cardiac tonics, and the subcutaneous injection of fluid, prescribed on the assumption that the patient suffers from uræmia. The author has observed three such prostatectomy cases, and he gives detailed records of two of them. The first patient died thirty-six hours after the operation. In the second case blood transfusion was performed, and was, in the author's opinion, the means of saving the patient's life, for as much as 10 ounces of urine were secreted during the first four hours following the transfusion. The author concludes that shock, loss of blood, and possibly infection, are the chief causes of death in these cases, and that transfusion of blood is the most rational treatment.

## Therapeutics.

#### 443. Novarschobenzol in Ulcerative Recto-colitis.

G. DURAND (*Bull. Soc. de Thé.*, February 11th, 1925, p. 62) remarks that ulcerative recto-colitis has become much more frequent since the war. The disease is characterized by the evacuation once or several times a day of mucopurulent or haemorrhagic discharges from the bowel, with or without faecal material. It begins insidiously in constipated subjects, or the onset may be violent, simulating acute dysentery. When once established the affection always pursues a chronic course, with or without acute paroxysms of diarrhoea or dysenteriform symptoms. Although the clinical picture is fairly characteristic, endoscopy is indispensable in order to determine the etiology and demonstrate the extent of the disease, as well as to avoid early carcinoma of the rectum or sigmoid being mistaken for congestive or ulcerative enteritis. Amoebic dysentery, which, according to Durand's personal experience, represents one-third of all cases of ulcerative recto-sigmoiditis, can also be excluded by endoscopy. All cases of chronic ulcerative recto-sigmoiditis should be treated by local measures, whether the condition is due to chronic dysentery or the cause is unknown. In the case of dysentery specific treatment by subcutaneous or oral administration of emetine, arsenic, or the double iodide of emetine and bismuth, almost always produces improvement, though rarely a permanent cure. In cryptogenic recto-sigmoiditis local treatment is the only method that should

be employed. In view of the good results obtained by Taillandier from rectal administration of arsenobenzol in the treatment of chronic amoebic dysentery which had proved refractory to ordinary measures, Durand applied this method in 28 cases of cryptogenic ulcerative recto-sigmoiditis or rectocolitis, with the following results: in a quarter of the cases a permanent cure was obtained after one year; in half the cases the ulcers cicatrized after a fortnight's treatment, but relapses occurred, due to erosive or congestive recto-sigmoiditis; and in the remaining quarter improvement, shown by diminution of suppuration and cessation of haemorrhage, was not maintained, so that the same treatment had to be recommenced or other measures had to be employed. The dose of arsenobenzol, which is administered in meringe, is 0.45 cg. at first; it is then rapidly increased to 1 gram, while in particularly severe cases 1 gram may be given from the first. About 20 to 30 drops of laudanum should be added, to enable the arsenobenzol to be retained for at least twelve hours. The injections are given every three days; in most cases five are sufficient.

#### 444. Late Syphilis treated with Cholesterin Compounds.

A. SATTA (*Rassegna di Clin., Ter. e Sci. affir.*, November-December, 1924, p. 234), who records ten illustrative cases, states that Serrero has recently introduced a new anti-syphilitic remedy under the name of "colicosan," each ampoule of 1 c.cm. containing 1 cg. of metallic mercury, 5 cg. of organic iodide, and 4 cg. of cholesterin. Satta's conclusions are as follows: (1) The compound can be substituted with advantage for all the mercurial preparations hitherto employed in the treatment of late syphilis and syphilis of the nervous system. (2) The compound is well tolerated, and does not present the drawbacks of the soluble and insoluble salts of mercury, though possessing all their advantages. (3) Its energetic specific action is combined with a remarkable tonic effect which gives it a special value in those forms of syphilis in which, in addition to the specific infection, there are symptoms of neurasthenia and loss of flesh. (4) The new preparation is of special value in the meningeal and radicular forms of syphilis which resist the ordinary treatment by mercury and arsenobenzol. (5) It exercises a favourable influence upon the Wassermann reaction.

#### 445. Intraperitoneal Injection of Antitoxin.

JOHN A. TOOMEY, OTTO L. GOEHLE, and CARL C. DAUER (*Amer. Journ. Dis. Child.*, February, 1925, p. 214) have treated 168 cases of diphtheria with antitoxin injected intraperitoneally. Commercial antitoxin was used, audited with saline solution. The advantages claimed for this method are: (1) that the antitoxin is absorbed rapidly from the peritoneum, up to seven hours the absorption being about five times that of the intramuscular injection, the membranes disappearing as rapidly with intraperitoneal injections as with intravenous; (2) the avoidance of a severe reaction with chill; 10 per cent. of the patients had a chill after intramuscular injections, 76 per cent. after intravenous, and 12 per cent. after intraperitoneal. The authors maintain that the intraperitoneal method is safe and simple and is the method of choice in severe cases of toxic myocarditis.

#### 446. Intraperitoneal Injection of Blood.

E. KLINGE (*Zentralbl. f. Chir.*, January 31st, 1925, p. 233) states that the action of intraperitoneal injection of blood is not so much due to an increase in the amount of the recipient's blood as to the vigorous chemico-biological stimulus which results from absorption from the extensive peritoneal surface. rise in the haemoglobin content coincides with an increase in the number of the red corpuscles. Klinge regards the method as less indicated in cases of acute anaemia which necessitate filling of the vascular system than in cases of chronic anaemia which are refractory to other methods of treatment, such as pernicious anaemia, leukaemia, cachexia due to malignant growths, malaria, tropical anaemia, ankylostomiasis, syphilis, and chronic tuberculosis, as well as in parenchymatous haemorrhages. Some 10 to 30 c.cm. or more of blood are injected midway between the umbilicus and symphysis pubis, or midway between the umbilicus and left anterior superior iliac spine, after the bladder and rectum have been emptied. Klinge employed the method in two cases of pernicious anaemia with the following results: In the first case, which occurred in a man aged 60, considerable improvement set in within a fortnight after the injection, and lasted for a year; a relapse then occurred and death ensued eight days after another intraperitoneal injection. In the second case, which occurred in a man aged 40, who had been suffering from pernicious anaemia for nine months, transient improvement occurred after intraperitoneal injection of 30 c.cm. of blood, but death took place within a month.

## Radiology.

#### 447. Intrabronchial Injection of Lipiodol.

E. LEURET and H. SECOURSSE (*Gaz. Hebdom. des Sci. Méd. de Bordeaux*, January 11th, 1925, p. 19) discuss certain technical difficulties and complications encountered when using Lipiodol in the skiagraphy of pulmonary diseases. The authors prefer Sicaud's intercrico-thyroid technique because of its simplicity and trustworthiness. They use an ordinary transfusion needle which has a calibre large enough to permit the oil to flow freely, but remark that its large size may increase the difficulty of piercing the crico-thyroid membrane, since the trachea may be displaced laterally by the necessary pressure, especially if the patient has not been warned to resist the tendency to swallow. When in the lumen of the trachea the needle-point is mobile, and on deep breathing or coughing air whistles through it. They use 1 per cent. solutions of novocain and Lipiodol, previously warmed to body temperature. The first few drops of novocain solution may cause slight transient cough; after injecting 8 c.cm. it is necessary to wait for six or eight minutes to obtain anaesthesia. Sicaud uses only 3 c.cm. of novocain solution, but the authors find the larger dose quite safe if the heart has been found to be healthy by careful examination and coffee has been given. During the six or eight minutes' interval the patient is placed in the most suitable position for the descent of the oil to the region that has to be examined. It is inadvisable to inject the whole quantity when the patient is in dorsal decubitus, as there is a partial diffusion throughout both lungs. The authors, when injecting either base, place the patient in a semi-sitting position, leaning towards the side which it is desired to inject. To inject either upper lobe the patient should lie on the affected side with the pelvis and head raised. When the middle lobe is to be injected lateral decubitus is required. For an adult 30 to 40 c.cm. of Lipiodol is used. The patient is instructed to avoid coughing and the head should be raised to prevent flow of the oily solution into the pharynx. To obtain good definition the plate should be placed under the patient as close as possible to the position of the Lipiodol, and the patient should be moved as little as possible. This technique, they find, ensures the best results. There were remarkable variations in the time required in different cases to procure disappearance of the Lipiodol; in one case it had almost disappeared in thirteen days, in others it was plainly visible for periods up to three months. In one case of interlobar empyema the patient's condition improved so greatly that a second "therapeutic" injection was given eight days later. The authors consider that this aspect of the injection is important. Several patients had transient fever, and in one case injection was followed in two days by a scarlatiniform erythema, and abdominal pain; on the fourth day, there was a slight haemoptysis.

#### 448. X-ray Treatment of Prostatic Hypertrophy.

KRABBE (*Zentralbl. f. Chir.*, February 7th, 1925, p. 315) records the good results obtained by his predecessor Longard and himself in the x-ray treatment of enlarged prostate. Since 1914 this method has been employed by them in all cases of this kind. In 23 out of a total of 28 cases x-rays produced a complete freedom from all symptoms for the next five years, and 5 returned with a recurrence, but in two of these repetition of the treatment again caused considerable improvement. Of five other patients who had recently been examined four were completely cured and one had occasionally a return of his old trouble. JANSSEN (*ibid.*) states that he has obtained excellent results from x-ray treatment of enlarged prostate where there was hypertrophy of the glandular part rather than of the connective tissue stroma. MARWEDAL (*ibid.*) also confirms the good results obtained in many cases of treatment of prostatic enlargement by x-rays. It was impossible to say in advance what course would be suitable for x-rays, especially as the nature of the prostatic hypertrophy could not be determined with certainty. Marwedal is in favour of continuing x-ray treatment even at the risk of occasionally overlooking carcinoma of the prostate.

#### 449. The Prognostic Significance of Haudek's Notch.

J. FRANDSEN (Copenhagen) (*Acta Med. Scand.*, February 12th, 1925, p. 481) states that it is now generally accepted that Haudek's notch, which appears in a skiagram as a more or less conical projection from the lesser curvature, varying in size from that of a pea to that of a walnut, is due to a penetrating ulcer. Ghneil (1919) reported 36 cases of gastric ulcer with Haudek's notch demonstrable by x-rays. In 32 of these cases the notch and the subjective symptoms disappeared under medical treatment; in 3 cases the notch became distinctly smaller under treatment, while 1 patient died from

haemorrhage. Fraudsén now reports 6 new cases which confirm Olund's observations; he has found that in duodenal ulcer the characteristic deformity of the duodenum also disappears in favourable cases. He claims that modern medical treatment, with restriction to an egg and milk diet, offers a good prospect of cure, and should receive prolonged trial before submitting the patient to surgical treatment. Repeated examinations by x rays will give very valuable information regarding disappearance of deformities of the lesser curvature or of the duodenum.

#### 450. Radiological Diagnosis of Cancer of the Oesophagus.

A. P. MARSELL (*Rev. med. de Barcelona*, February, 1925, p. 102) states that carcinoma of the oesophagus presents the following radiological appearances which distinguish it from other causes of oesophageal stenosis: (1) A tumour is sometimes seen forming part of the wall of the oesophagus. (2) There is a sudden and irregular termination of the lumen of the oesophagus. (3) The stenosed portion is extremely irregular in outline, there being stenosis and dilatation without a complete obstruction of the lumen of the duct. (4) The dilatation above the lesion is not very marked. (5) The peristaltic wave comes to an end at the stenosed portion.

#### 451. Radium in Hypertrophy of the Prostate.

KOGAN (*Journ. d'Urol.*, January, 1925, p. 23) gives her conclusions on the results of the treatment of simple hypertrophy of the prostate with radium. In 6 cases 3 patients recovered the act of micturition, 1 was markedly improved during a period of three years, and in the remaining 2 the symptoms were somewhat relieved. The radium caused shrinkage of the enlarged gland; in some cases this action was very marked. Another important point mentioned is that radium does not in any way increase the difficulties of the surgical removal of the gland if this should be decided on later. The radium was introduced in a specially constructed type of urethral catheter containing two canals, a lower one for the radium tube and an upper one which allows the urine to escape. It was easily introduced and caused little discomfort to the patients. Applications can also be made from the rectum in a specially constructed bougie; two or more applications are generally necessary before the full effect is obtained. Kogan concludes that in cases unsuitable for operation where a catheter life is necessitated the condition of the patient may be improved by radium treatment.

## Obstetrics and Gynaecology.

#### 452. Uterine Mucosa in the Fallopian Tube.

B. SCHINDLER (*Zentralbl. f. Gynäk.*, March 14th, 1925, p. 582) states that in this abnormality, seldom described hitherto, the tubal epithelium may be partially or completely replaced by a mucosa having a similar structure to that of the uterine cavity. Webster (1896) described the first case. In a tubal pregnancy he found typical uterine mucosa lining the Fallopian tube; there was no evidence of a previous salpingitis. Schridde and Schönholz have reported two similar cases; in one the glandular structure was coextensive with the tube, in the other the uterine mucosa extended only to the isthmus. Schindler refers to three other published cases and describes a new one. An unmarried woman, aged 42, had multiple uterine and tubal adenofibromata, a right haematosalpinx, invasion of the right ovary by heterotopic epithelium with a psammomatous formation, and a right corpus luteum cyst. He illustrates the histological findings with two plates. The characteristic uterine mucosa almost filled the lumen of the tube, which was considerably distended. He adds that this condition is probably a frequent cause of tubal pregnancy.

#### 453. Treatment of Eclampsia.

K. M. WILSON (*Amer. Journ. Obstet. and Gyn.*, February, 1925, p. 189) states that at the Johns Hopkins Obstetrical Clinic much better results have been obtained by conservative than by radical treatment of eclampsia. In a series of 110 cases treated up to 1912 the maternal mortality was 23 per cent. The primary therapeutic objective in these cases was immediate delivery: only two undelivered patients were delivered spontaneously, and instrumental delivery, the vaginal hysterectomy of Dührssen, or abdominal Caesarean section was performed in a large proportion of cases. In 1912 more conservative lines of treatment, with free venesection, were adopted, and in 137 cases treated since then the maternal mortality has been about one-half of that of

the former series. Since 1912 spontaneous labour occurred in about 43 per cent. of cases, and operative intervention was limited to low forceps application or version, and extraction after spontaneous cervical dilatation. Since 1912 conservative treatment has become increasingly the rule. The patient is kept lying quietly on her side in a darkened room and is given hypodermically morphine gr. 1/4, which may be repeated during the next twenty-four hours. Venesection up to 1 litre is performed, while the pulse and blood pressure are watched. Water is given freely during consciousness, and in coma 500 c.cm. of 5 per cent. glucose solution is given intravenously. In the absence of any definite maternal indication other than the eclampsia no attempt at delivery is made unless the cervix has completely dilated. Wilson has divided the cases into mild and severe according to Eden's classification, and finds that conservative treatment has reduced the mortality in severe cases from 39 to 19 per cent. It is to be noted, however, that in the conservatively treated group five women died undelivered. He points out that if stillbirths, deaths within two weeks of birth, and cases of maternal death before delivery be counted the foetal mortality was practically the same in the radically and conservatively treated cases. He concludes that radical operative procedures should have no further place in the treatment of simple eclampsia, and agrees with Eden that in the comparative analyses of therapeutic results it is most important to distinguish between mild and severe cases.

#### 454. Cervical Incisions in Dystocia.

FAVREAU (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, 1925, II, p. 155) favours making incisions of the vaginal portion of the cervix in certain cases of dystocia, and records two illustrative cases. This operation must only be performed when the obstruction to delivery proceeds from rigidity of the soft parts, since in other cases there is risk of the incision leading to rupture of the lower uterine segment. The indication is based on the degree of effacement rather than of dilatation of the cervix; the incision is useless in a well dilated sleeve-like cervix which has not become thinned out and is not yet exposed to pressure by the presenting part. An oedematous rigid cervix is frequently infected, but according to Favreau infection is not a contraindication to incision. GAUTRET and LAPREVENCE (*ibid.*, p. 150) record a case of cervical rigidity impeding the delivery of a small foetal head treated by anterior and posterior cervical incisions; within a year the patient again became pregnant, and she was delivered without difficulty or complications of a full-time infant presenting by the breech after prematernal rupture of the membranes.

#### 455. Intrauterine Transplantation of the Ovary.

H. HARTMANN (*Gynécol. et Obstét.*, 1925, xi, 1, p. 38) describes the two operations of Tuffier and of Estes for implantation of ovarian tissue into the uterus. In both a portion of the ovary is first resected, and in both the implanted portion is made to retain its original arterial blood supply. No mortality has been recorded from the operation. In all these cases both Fallopian tubes had been excised. Of Tuffier's twenty-nine patients all continued to menstruate, and one subsequently gave birth at term to a living child; of the twenty-seven patients whose after-history Estes was able to trace all save one continued to menstruate, two became pregnant but aborted at the third month, and four carried two pregnancies to a successful termination. Hartmann regards the operation as one which is justifiable, ensures persistence of menstruation, and may permit conception and parturition. The existence of undetected accessory ovaries may be suspected in certain cases, but in one of Tuffier's cases ovulation was demonstrated in the uterine transplant of ovary after its removal at a subsequent operation.

#### 456. The Cause of "After-pains."

MONTUORO (*Rivista d'Obstet. e Gynecol. Prat.*, February, 1925, p. 90) is convinced that if the uterine contractions occurring intermittently during the first few days after labour are associated with severe pain, the cause is not a specially nervous condition of the patient, but the intrauterine retention of ovular remnants, of blood clot, or of a submucous myoma. After-pains, he believes, are always expulsive. Treatment should be directed primarily to emptying the uterus; this may be accomplished in the first hours after labour by manual expression, and in the first three days as a rule by massage and administration of ergot; instrumental clearing out may be required occasionally in a very voluminous uterus. Administration of sedatives is called for, but should not, as it sometimes does, constitute the whole treatment.

## Pathology.

### 457. Diagnosis of Gall Stones.

E. MEULENGRACHT (*Arch. Intern. Med.*, February 15th, 1925, p. 214) stresses the importance of examining the blood for bile pigment and the urine for urobilin, as indications of occult jaundice in the diagnosis of gall stones. The increase of bile pigment in the blood plasma must reach a certain height before jaundice of the skin and sclerotics occurs, and before bile appears in the urine. The bile pigment in the blood plasma is detected by taking 3 c.cm. of blood from a vein and placing it in a small test tube containing two drops of a 3 per cent. solution of sodium oxalate. The tube is inverted a few times, allowed to stand twenty-four hours, and then 0.5 c.cm. of the plasma is pipetted into a graduated tube, and diluted with saline solution until the colour matches a standard. The author advocates routine examination of the blood plasma, when jaundice of the skin, or bile in the urine, is doubtful, in a case of suspected gall stones. The diagnostic value of urobilin in the urine, after an attack of gall stones, has been pointed out by S. Hansen. Gall-stone attacks may occur without jaundice, and jaundice may be due to other causes. What is characteristic of a gall-stone attack is that transient jaundice of short duration occurs in conjunction with pain resembling gall-stone colic. When jaundice is manifest further investigation is unnecessary; but in occult jaundice examination of the blood and urine may be desirable. In private practice blood examination is preferable, since a twenty-four hours' sample of the urine is required for the urobilin test. The examination must be made just after an attack of pain.

### 458. Diagnosis of Spirochaetosis Icterohaemorrhagica.

V. VANNI (*R. Policlinico, Sez. Prat.*, January 19th, 1925, p. 81) states that the methods most frequently used for the diagnosis of spirochaetosis icterohaemorrhagica are: (1) agglutination of the spirochaete of Ido and Inada by the patient's serum; (2) inoculation of the patient's blood or urine into a guinea-pig, and examination of the organs, especially the liver and kidneys, for the spirochaete, after the animal has succumbed to the infection. The agglutination test, however, is not easy to perform owing to the difficulty of obtaining pure cultures and keeping them alive. The inoculation test proves positive in only a limited number of cases, as guinea-pigs resist infection by certain strains of *Spirochaeta icterohaemorrhagica*. Moreover, the death of the guinea-pig is often delayed till after that of the patient. Vanni suggests a more rapid method, which consists in injecting 5 c.cm. of the patient's urine into the peritoneum of a guinea-pig of average weight. Puncture of the heart is made forty-eight hours later, when the blood is examined for the spirochaete, either directly with the ultramicroscope or according to the methods of Fontana, Leishman, or May-Grünwald-Giemsa. Another method, which is less certain and slower, but possesses the advantage of dispensing with guinea-pigs, is cultivation of the urine. About 4 or 5 c.cm. of urine are mixed with an equal quantity of normal horse serum, diluted to one-third with normal saline, and the whole rendered alkaline with sodium bicarbonate in a test tube containing a piece of fresh tissue of a rabbit or guinea-pig, and covered with a layer of about 1 c.cm. of vaseline so as to secure anaerobiosis. Under such conditions the organisms will develop in three to five days.

### 459. The Blood in Typhoid Fever.

J. SABRAZÉS (*Gaz. hebdom. Sci. Méd. de Bordeaux*, January 25th, 1925, p. 51) states that it is only during the first few days of typhoid fever that there is a very slight leucocytosis of twenty-four to forty-eight hours' duration, which is followed by leucopenia in 92 to 95 per cent. of all cases. The number of white cells falls to 5,000, 4,000, or 3,000, and in very severe cases below 1,000. The leucopenia lasts till the fourth week, and then as a rule the number of white cells returns to normal. As regards the differential count the number of neutrophils per cubic millimetre, instead of the normal 4,000, falls to 2,000 and lower with a percentage of 40 to 50. The nuclei of the neutrophil cells show pathological changes in the form of pyknosis, fragmentation, and vacuolization. When the temperature has become normal, the number of neutrophil polymorphonuclears also returns to the normal. At the onset of typhoid fever the eosinophils become much reduced in number and even disappear, but return in the third or fourth week and gradually increase in number, so that in convalescence there is an eosinophilia of 15 to 25 per cent., which persists for some time. In the first two weeks the lymphocytes participate in the general reduction of the white cells, and may fall from 1,200 to 100 per cubic millimetre. At the end of the second week their percentage

rapidly increases, and henceforth the number of lymphocytes exceeds that of the neutrophils per cubic millimetre. In convalescence the lymphocytosis diminishes, but is still fairly well marked. On the other hand, on the occurrence of complications the number of lymphocytes tends to fall, sometimes to a considerable degree. Plasma cells, Türk's irritation cells, and a few myelocytes are sometimes found. The various complications of typhoid, such as peritonitis, haemorrhage, otitis, bronchopneumonia, and cystitis, may modify the blood picture by giving rise to leucocytosis or polymorphonucleosis. If in spite of the existence of a complication such as peritonitis or pneumonia, leucocytosis is absent or small, the prognosis is grave, since this indicates an absence of reaction and an inhibition of cellular regeneration in the bone marrow. Relapse of leucopenia and anaemia is sometimes very marked after antityphoid vaccination is the same as in typhoid fever, being characterized by a persistent leucopenia and lymphocytosis.

### 460. Traumatism and Cancer.

J. THOMAS (*La Vie Médicale*, February 13th, 1925, p. 231) refers to a publication in 1924 by C. Stajano (Monte Video) in which are described the immediate and remote effects of nerve injuries, the clinical effects of peripheral neuritis on the central nervous system, and the influence of traumatism on the development of cancer. Stajano found that in all injuries the nervous system took part in the evolution of the lesion, and it is suggested that lingual leucoplakia, for example, commences as an epithelial dystrophy in response to disturbance of a trophic nerve centre by an irritating agent such as a carious tooth. Stajano's experiments indicated the existence of a nerve factor in the production of leucoplakia and of the cancer which develops in it. The fact that cancer occurs more frequently in certain regions than in others is explained by him as being due to differences of innervation. Thomas thinks that describing cancer as due to cellular anarchy mistakes effect for cause and that it would be better to say that cancer commences as a cellular disorientation. Since all organic functions are regulated by the nervous system, this system ought to be regarded as the origin of all derangements of function. A systemic reaction so profound as that produced by cancer cannot be due to the fact that a group of cells is in a state of anarchy; that must be a consequence only, and the cause must be sought elsewhere. He believes that the part played by syphilis and tuberculosis in originating precancerous dystrophies is the production of fibrotic and destructive changes in the nervous system. He urges, therefore, that traumatism in general and chronic ulceration in particular should be regarded as extending beyond the limits of the organ or of the region and affecting simultaneously all the regional nerve supply.

### 461. Differential Staining of Living and Dead Bacterial Spores.

S. A. KOSER and J. H. MILLS (*Journ. of Bacteriol.*, January, 1925, p. 25) report some experiments made to determine whether it is possible to ascertain the number of living and of dead spores in a bacterial culture by means of their reaction to staining fluids. Working with heated spores of *B. megaterium*, they found that when stained by a modified Ziehl-Neelsen method about 98 per cent. showed the ring type of staining, whereas the remaining 2 per cent. showed the solid type. On the other hand, spores which had been killed for an hour at 100° C. showed uniformly the solid variety. That is to say, dead spores are stained evenly and solidly, whereas living spores stain only round the periphery. That this method was trustworthy in estimating the proportion of living to dead spores was shown by mixing known numbers of the two kinds and counting the proportion of ring to solid forms, when it was found that the actual agreed closely with the calculated results. Experiments with other spore-bearing organisms, such as *B. mesentericus*, *B. subtilis*, *B. cereus*, and *B. ramosus*, gave similar results, but with *B. terminalis* and *B. fusiformis* a marked discrepancy was found. It is clear that not all species of bacterial spores are alike in their reaction to stains, and even amongst the first group minor differences were found in the time and in the temperature which were required to obtain the best results. In a further experiment an old culture of *B. megaterium*, consisting almost entirely of spores, was heated at 90° C., and the number of surviving organisms after varying times was calculated both by the staining method and by plate counts. Up to thirty minutes there was a strong disagreement between the two methods, the plate count showing a much higher percentage of dead organisms; after this time the agreement was perfect. This seems to show that spores are rendered incapable of germination somewhat earlier than they become penetrable by dyes.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 462. The Schick Reaction and Passive Immunity to Diphtheria.

G. FRONTALI and M. RASPI (*Riv. di Clin. Ped.*, February, 1925, p. 73) examined the Schick reaction in 413 normal Florence children, aged from 1 month to 12 years, with the following results. (1) 26.1 per cent. were positive—a figure considerably below that found in Vienna and New York children (60 per cent.). (2) The frequency curve commenced with a minimum of 20 per cent. in the first year, reached a maximum of 38.5 per cent. between the second and fifth years, and then gradually fell to 25.7 per cent. between the fifth and eighth years, and to 23 per cent. between the eighth and twelfth years. (3) Among 161 diphtheria patients the reaction, which was intensely positive before treatment, became invariably negative after serum treatment and remained negative until twenty days after the last injection of serum. Intramuscular injection of 3,000 to 5,000 units two to three hours after intradermic injection of toxin had not the power to inhibit the appearance of a positive reaction. It was only when the test was performed after the injection of 3,000 to 5,000 units that the reaction was negative. In two cases intradermic injection of toxin performed simultaneously with intravenous injection of 5,000 units of antitoxin was followed by a negative reaction. When the test was made three to six hours after intramuscular injection of 2,000 to 5,000 units of antitoxin, it was always negative. (4) The reaction remained negative after the appearance of serum eruptions. (5) In diphtherial paralysis the reaction was positive if the patient had had no serum, but was always negative when serum had been given in the acute stage. (6) The frequency of positive reactions was greater in measles (60 per cent.) and in scarlet fever (51.8 per cent.) than in normal children. (7) The repetition in series of the Schick reaction did not have an immunizing effect. (8) Normal horse serum like antidyseric and antineurococcic serum in doses of 30 c.cm. for children weighing 12.2 kilos may inhibit a positive reaction. (9) To obtain the same effect with diphtheria antitoxin 2.5 units per kilo of body weight are sufficient. (10) In guinea-pigs weighing 500 grams 0.5 to 0.6 c.cm. of normal horse serum is needed to make the Schick reaction negative, while the same result is obtained with 0.5 antitoxin units contained in 0.00012 c.cm. of diphtheria antitoxin—that is, in a volume of serum 5,000 times smaller.

### 463. Paroxysmal Oxaluria.

F. LOMMEL (*Med. Klin.*, February 6th, 1925, p. 194) points out that the term "oxaluria" indicates merely that the urine recently passed contains a large quantity of crystals of calcium oxalate; it does not refer to the amount of oxalic acid the urine contains. The author applies the term "paroxysmal oxaluria" to the paroxysmal occurrence of such sediments in the urine, with characteristic symptoms, of which the most important are severe renal pains like those of renal colic. The urine usually contains, in addition to the numerous crystals of calcium oxalate, a small quantity of blood; in the intervals between the attacks both are absent from the urine. The author records in detail the clinical history of one case. He thinks that the attacks possibly depend on altered conditions of solution and precipitation of oxalic acid, and the relation of this to colloid substances in the urine is discussed. If the calcium oxalate is precipitated in the kidney, as is probable, it is easy to understand why haematuria and pain occur. The attacks in many cases cease spontaneously; in other cases they are terminated by a complete change in the mode of life, with diminished strain on the nervous system. The author has not been able to decide if dietetic measures or certain drugs have any beneficial effect.

### 464. Pulmonary Tuberculosis in Childhood.

F. G. CHANDLER and T. W. PRESTON (*Brit. Journ. Child. Dis.*, January-March, 1925, p. 1) record their observations on a study of nearly 300 cases of pulmonary tuberculosis in children during the last twelve years. Although the diagnosis of pulmonary tuberculosis was definitely proved in only 89 by finding tubercle bacilli in the sputum or by autopsy, the rest were probably early cases of pulmonary or possibly hilar tuberculosis. The ages of the 89 patients whose histories are set forth in tabular form ranged from 3 to 14 years. In all the cases the lungs, or perhaps the mediastinal glands, were primarily affected. No examples of

miliary tuberculosis were included, with the exception of three children who were admitted with obvious pulmonary tuberculosis and died of a terminal miliary affection. Of these 89 children 61, or 68 per cent., were females and 28 were males; 39 were 12 years and under, and 22 were 10 years and under. As the result of treatment 35 were improved, 19 were discharged with the condition unchanged, 27 died, and 2 were still in hospital. The authors' conclusions are as follows: Pulmonary tuberculosis does occur in infancy and childhood, and is not extremely rare. It may run a long chronic course, and is not necessarily fatal. The stronghold of the disease is the bifurcation and bronchial glands, and the lungs are probably infected from this source. Before a diagnosis of intrathoracic tuberculosis is made every care should be taken to exclude other chronic infections, but when this has been done there should not be too great a reluctance to diagnose tuberculosis, especially when such symptoms as cough, febrile attacks, and poor nutrition are predominant features.

### 465. Herpes Zoster and Varicella.

B. C. AYIRAGNET, J. HUBER, and DAYRAS (*Bull. et Mém. Soc. Méd. Hép. de Paris*, February 12th, 1925, p. 185) report the case of a girl, aged 14, suffering from concurrent herpes zoster and varicella. The herpes appeared as three distinct patches, the first being in the seventh intercostal space external to the left breast, and the second and third in the tenth and eleventh intercostal spaces respectively. They also describe a case in which typical crural and gluteal zoster in a boy, aged 5, was followed fourteen days later by varicella in his two brothers. The authors conclude that the virus of varicella has a special and sometimes an exclusive affinity for the posterior ganglia. They maintain that some zoster, whether pure or associated with typical varicella, are of the varicella nature, and that the time has come to add to the classical description of varicella two clinical forms of the disease—one zoster-varicella, and the other the pure zoster form of varicella. COMBY (*ibid.*, p. 192), while admitting that varicella may give rise to zoster in the same way that whooping-cough, measles, scarlet fever, typhoid fever, and especially tuberculosis do, disputes the contention that zoster may give rise to varicella, and regards such cases merely as coincidences. A. NETTER (*ibid.*, p. 192) mentions two cases of generalized varicella coinciding with herpes zoster, the eruption being so profuse in one case that the patient was certified as suffering from small-pox. In 76 out of 78 cases of zoster of all kinds Netter and Urbain claim to have established the existence of varicella antibodies. Netter therefore concludes that zoster is not merely a specific infectious disease as Landouzy has maintained, but is usually, if not always, a manifestation of varicella infection.

## Surgery.

### 466. Torsion of the Spermatic Cord.

G. MASSA (*Il Policlinico*, Ann. 32, February 2nd, 1925, p. 164) reports two cases of this uncommon condition. (1) A boy, aged 14, whilst sitting quietly was seized with severe pains in the right testis, which increased in intensity and was accompanied by tenderness. A few hours later the testis was found to be much larger than usual, and movable to a certain extent. There was no history of injury, hernia, or urethral trouble. Under local anaesthesia the swelling was explored and it was found that the spermatic cord was completely twisted on itself in a direction reverse to the ordinary movement of a clock. The testis was engorged and cyanotic, there was an unusually roony tunica vaginalis, and the vessels of the cord were separated into two bundles. The cord was untwisted, and complete recovery followed without any atrophy of the testis. (2) A man aged 26, after a long bicycle ride, noticed pain in the right scrotum. A few days later a condition similar to the first case was seen, and on operation the cord was found to be twisted, the testis cyanotic and engorged, with signs of atrophy. The cord was untwisted, but part of the testis ultimately became necrotic and atrophy developed. The different result in the two cases illustrates the advantage of treating these cases early. In differential diagnosis the chief difficulty is the possibility of hernia, which may coexist. The degree of twisting varies, but even a small twist soon affects the testis, so that early operation is advisable.

## 467. "Red Stomach."

J. SCHOEMAKER (*Surg., Gyn. and Obstet.*, March, 1925, p. 305) remarks that every surgeon has experience of performing laparotomy for gastric or duodenal ulcer and finding neither present. He has noticed that in some of these cases the pyloric portion of the stomach showed a vivid red colour: the stomach was usually normal in size and there were no signs of induration or ulcer. Moynihan described a somewhat similar condition secondary to inflammation elsewhere in the abdomen, generally in the appendix. Schoemaker has some conclusions on 45 cases of this so-called "red stomach." In 17 gastrectomy was performed, and in these cases there was intense hyperaemia of the serosa. The appendix was only affected in 4 cases and so could not be considered to be the cause of the condition. Removal of the appendix in 6 cases did not relieve the symptoms. In 3 cases the gall bladder was found to be diseased and was removed, with good results. Schoemaker thinks that the primary cause may be found in the sympathetic nervous system. The symptoms in such cases are pain after food with periods of latency, nausea, sour eructations, and rarely vomiting. Radiograms show a normal stomach with some retention. He advises that when a red stomach is found on laparotomy the gall bladder should be examined. If it is normal the abdomen may be closed or gastrectomy be performed. Gastrectomy has but a slight risk and is simple in these cases; in 50 per cent. the patients are healed. Therefore the author gives his patients the 50 per cent. chance, and considers the reasons are sufficient for performing a gastrectomy in these cases.

## 468. Secondary Growths of the Bones.

P. DELBET (*Bull. Assoc. Franç. du Cancer*, January, 1925, p. 10) remarks that tumours of the skeleton are often thought to be primary when in reality they are secondary to a growth elsewhere in the body. Operations for their removal are therefore useless. He states that tumours of bone which reveal themselves in the first instance by a spontaneous fracture are usually secondary and are not osteosarcomata; tumours arising in the diaphysis are more often secondary than primary growths, and multiple tumours of bone are usually secondary growths. Spontaneous fracture in an osteosarcoma occurs usually late in the disease and the presence of the tumour has been already recognized. In secondary growths, however, it may be the first manifestation of the condition, even before there is any obvious swelling. Delbet finds that the majority of primary bone tumours, innocent or malignant, start in the epiphysis or juxta-epiphyseal region. Periosteal sarcomata arising in the shaft of the bone are uncommon. He concludes that when a tumour of bone is discovered, either through a spontaneous fracture or arising in the shaft, a very thorough examination is necessary before any operation, since the primary growth may be very small or situated in the viscera and be difficult to discover. Delbet reports a case of carcinoma of the breast in which secondary growths were present in the upper limb and in the pelvis. In another case, after resection of the humerus for a spontaneous fracture of it, secondary deposits were found subsequently in most of the bones and also in the viscera. The primary site in this case could not be discovered.

## 469. Peptic Ulcer of Meckel's Diverticulum.

J. SENEQUE (*Presse Méd.*, February 18th, 1925, p. 221) has collected 8 cases of peptic ulcer of Meckel's diverticulum, including Brasser's case (*Epitome*, December 13th, 1924, para. 465). In 4 cases the lesion was only discovered at autopsy; in the other 4 cases it was found in the course of an exploratory laparotomy, and all these patients recovered. Seneque draws the following conclusion from the published cases. When symptoms of haemorrhage or of peritonitis occur in the course of an exploratory operation without obvious cause it is important to ascertain whether Meckel's diverticulum is diseased. In the 4 cases which recovered, the original diagnosis was incorrect, but a careful search revealed the actual lesion. Thus the class of cases of "primary peritonitis" has been further restricted and it is probable that other cases of this condition will be reported. Until 1913 no case had been reported, while in 1924 three cases occurred. In regard to etiology, all the patients were males; 5 patients were between 6 and 13 years of age. The patient of Hallopeau and Humbert was only 11 months old, while the patient operated upon by Mégeant and Dunant was 28 years of age. Hübbschmann's patient lived for four weeks after a fall of about 5 feet; it is possible that this fall hastened the perforation. Nearly all the ulcers showed macroscopically a more or less definite induration of the surrounding tissues. In 4 cases the ulcer was near the base of the diverticulum, in 3 cases near its apex, and in 1 case near its centre. As a general rule the perforation was lenticular. Gibbal noted the existence of a

band 3 mm. in thickness and 8 cm. in length attached to the caecum and ending in a tumour on the ileum situated about 50 cm. from the ileo-caecal angle. In Brasser's case the apex of Meckel's diverticulum was attached to the appendix without any communication with its lumen. Humbert has proved that in these cases the mucous membrane resembles that of the stomach, and therefore the ulcers are of the true "peptic" type. Seneque adds that haemorrhage is usually abundant and is generally of the melanotic type; hence the condition has been diagnosed as (a) duodenal ulcer, (b) tuberculous ulcer, and (c) polypus. Resection of the diverticulum is the operation indicated, but if on account of the patient's condition this is inadvisable the perforation must be closed, postponing resection of the diverticulum or of the ileum to a later date.

## Therapeutics.

## 470. Sanocrysin Treatment of Tuberculosis.

K. FABER (*Ugeskrift for Læger*, March 26th, 1925, p. 315) has treated 36 cases of pulmonary tuberculosis with sanocrysin between September, 1924, and March, 1925. The dose of the first intravenous injection was 0.5 gram, and the dose of the subsequent injections was usually 1 gram. The intervals between the injections were usually from two to six days, and it was found advisable not to repeat an injection until the febrile reaction from a previous injection had passed off. The disease in every case was more or less chronic, and there were no complications at the commencement of treatment. Of the 36 patients 3 were in desperate straits when the treatment was begun, and their early death could not be ascribed to it. There were two patients whose death was probably caused by the treatment, with which the author had at the time but little experience. Two other patients discontinued the treatment at their own request, although the physical signs indicated that it was beneficial. A patient suffering from pleurisy without signs of pulmonary disease recovered completely. There were also 12 patients who had not yet completed treatment, and who could not, therefore, be regarded as criteria of its efficacy, although all tolerated it well, and the sputum of some had ceased to contain tubercle bacilli. Thus there remained 16 patients who, having completed the treatment, and having been chosen for it as suitable cases, formed a material by which the value of the drug could be judged. The author gives full details of the first 4 patients in this group, and he points out that the remarkable recovery effected within a couple of months was such as is only seen under ordinary treatment continued for a much longer period. All but one of the first 7 patients in this group were freed from the tubercle bacilli in their sputum, and this patient had almost ceased to expectorate. Four other patients, whose pulmonary disease was of a fibrotic character, showed little change in the physical signs, but 3 had ceased to expectorate; they all felt much better, being no longer febrile and weak. The remaining 5 patients did not respond so satisfactorily to the treatment, which in some cases was, however, beneficial up to a certain point. Faber concludes that this treatment marks an important advance, and that it is particularly valuable in comparatively recent cases in which the disease is pneumonic rather than fibrotic. Patients with a high temperature are not as well suited for it—for this reason, among others, that the fever of the untreated disease masks the fever of the sanocrysin reaction, which must have subsided before another injection is given. Again, the severity of sanocrysin shock seems to be proportional to the height of the temperature at the commencement of treatment, and it is therefore well to defer it in febrile cases till the temperature has been reduced by other means. The author is doubtful about the value of intramuscular injections of sanocrysin, and has found that it does not always prevent or cure albuminuria. This he traces to gold poisoning rather than to sanocrysin shock, having found that, while the febrile reaction diminished as the injections proceeded, the albuminuria was apt to become more severe.

471. T. NEUMANN (*Tidsskrift f. d. Norske Læger*, March 15th, 1925, p. 292) reviews the latest experiences of Danish physicians with sanocrysin, the dosage of which has recently been considerably changed from that originally recommended by Moelgaard. The dosage which struck the author as being most safe and promising was that adopted by Bogason of the Søllerød Sanatorium. His aim is to avoid severe reactions and to increase the dosage very gradually. He begins with 0.05 to 0.1 gram by intravenous injection, increasing to 0.125, to 0.15, to 0.2, to 0.25, and so on, with intervals of four days between the injections. When he reaches a dosage of 0.3 gram he distributes the dose over two days, giving 0.2 on one day and 0.1 on the next. The results so far have been satisfactory, the patients being able to be up and about,

following the ordinary sanatorium routine. All the patients felt better, although they were fairly severe cases. In most cases the sputum and the number of tubercle bacilli therein dwindled. There was a gain of appetite and weight, and some of the patients became afebrile. There were no complications apart from slight diarrhoea, which responded readily to tannin enemas. The supplementary use of serum proved unnecessary with this cautious dosage, which has, however, been given a trial only for two months. With regard to the more heroic dosage, some institutions continue to give as large quantities as the patient can tolerate, whereas others do not exceed a dose of 1 gram at a time.

#### 472. Sanocrysin Shock or Gold Poisoning?

O. SCHEEL (*Tidsskrift f. d. Norske Lægef.*, March 15th, 1925, p. 289) records a fatality from sanocrysin, the circumstances of which suggest that death was due rather to gold poisoning than to the "tuberculin shock" which Moelgaard has described. The patient was a woman, aged 27, suffering from severe pulmonary tuberculosis, the prognosis of which, under ordinary treatment, was doubtful or bad. She was given four injections of sanocrysin, the doses being 0.5 gram followed by three doses of 1 gram each. The intervals between the injections were two, four, and seven days respectively. She was also given several injections of serum. During the treatment she suffered from loss of appetite, nausea, vomiting, diarrhoea, albuminuria, biccup, and oliguria. After the last injection there was almost complete suppression of urine, but no oedema. This injection was given on February 11th, and death occurred on February 13th. During the last hours of life there was increasing cyanosis, but no fall of temperature, and no sign of a focal reaction in the lungs. The necropsy showed hyperaemia and oedema of the lungs, hyperaemia of the colon, haemorrhages in the small intestine, and severe degeneration and necrosis of the kidneys. This parenchymatous disease of the kidneys, and the changes found in the intestines, were reminiscent of poisoning with mercury perchloride, and were probably due to direct poisoning with the gold salt. The absence of a fall of temperature, supposed to be characteristic of "tuberculin shock," is also interpreted by the author as indicating gold poisoning rather than a kind of Herxheimer reaction. In further support of this view the author notes that a Herxheimer reaction, due to the liberation of toxins by the action of a chemotherapeutic remedy on micro-organisms in the body, does not damage the kidneys when tuberculin is given to tuberculous guinea-pigs; it is only when such guinea-pigs suffer from tuberculosis of the kidneys themselves that an injection of tuberculin causes hyperaemia of the kidneys in the neighbourhood of the tubercles. Hence the author's conclusion that it is incorrect always to ascribe albuminuria and renal disease to the action of toxins set free by an injection of sanocrysin; they are probably due in the main to direct action of the gold salt on the kidneys.

## Anaesthetics.

#### 473. Prevention of Post-anaesthetic Vomiting.

E. SATTLER (*Deut. Zeit. f. Chir.*, February, 1925, p. 129) states that post-anaesthetic vomiting may be caused by two factors—namely, (1) direct stimulation of the medulla oblongata in the neighbourhood of the respiratory centre; (2) reflexly through the gastric branches of the vagus, and especially through the fibres ending in the neighbourhood of the cardiac orifice. Prevention of post-anaesthetic vomiting is effected by rapid removal of the narcotics stimulating the medulla, and by diminution of the stimulation of the gastric fibres of the vagus. Sattler has found that administration of lobelin was most suited for this purpose in the form of crystalline lobelin hydrochloride. After injection of this preparation the respiratory rate of the anaesthetized patient became twice as quick and also deeper and more intense. Sattler's observations, which were confirmed by Wieland in man and animals, were derived from the study of twenty-six patients, twenty-four of whom received either only and two chloroform as well. Only one patient, who had been operated on for fistula of the bile duct, vomited after the operation, and another suffered from nausea, but none of the other patients vomited or felt sick. The nature of the operations was as follows:—  
 Hicectomy  
 peritonitis  
 2; carcinoma  
 of jaw, 2; and carcinoma of femur, 1. The duration of the operation ranged from thirty-five to ninety minutes, and the

amount of ether used from 350 to 1,200 c.cm. Immediately after termination of the anaesthesia 1 c.cm. of lobelin was injected subcutaneously. Larger doses were never required. Sattler is at present conducting experiments to determine whether the effects of the lobelin are due to stimulation of the respiratory centre or to a direct action on the vomiting centre in the medulla.

#### 474. Headache complicating Spinal Anaesthesia.

CH. DUJARIER (*Bull. et Mém. Soc. Nat. de Chir.*, February 7th, 1925, p. 115) draws attention to the fact that headache is the most frequent complication after spinal anaesthesia. Following the advice of Chaput, he has frequently tried to relieve this by a further puncture to bring about decompression, but he was often unsuccessful and the cerebro-spinal fluid has been found to be under very low pressure. He has noted in some cases a profuse leakage of cerebro-spinal fluid through the skin puncture after injection, whilst in other cases it appeared probable that the fluid had leaked into the subcutaneous tissues; this would naturally result in a fall in pressure of the cerebro-spinal fluid. Dujariere considers that this lowering of tension of the cerebro-spinal fluid may be the cause of the headache, and he has noted the early occurrence of headache in those cases where an excess of fluid had been withdrawn. He therefore advises the use of a very fine needle for the puncture. When headache occurs he has adopted the intravenous injection of 10 c.cm. of distilled water, which usually relieved this symptom completely, either immediately or on the following day.

#### 475. Local Anaesthesia in General Surgery.

A. BERGAMINI (*Il Policlinico, Sez. Chir.*, March 15th, 1925, p. 113) remarks that in cases of strangulated hernia, intestinal obstruction, septic peritonitis, severe anaemia, and, generally speaking, every case in which organic resistance is reduced and the natural defences are paralysed by stercoræmia, septicaemia, or prolongation of the disease, the intoxicating and depressing action of a general anaesthetic is largely responsible for many operative failures, every hour of general anaesthesia by chloroform or ether being equivalent to the loss of a litre of blood. On the other hand, the advantages of local anaesthesia are numerous. Novocain, he thinks, is still the best local anaesthetic; not only is it six times less toxic than cocaine, but it possesses a high anaesthetic power. It is non-irritating and does not cause vaso-dilatation. The only point against it is the short duration of the anaesthesia produced by it, but this may be obviated by the addition of adrenalin, which by its constrictor action considerably increases the degree of anaesthesia, and at the same time prevents a rapid absorption of a large quantity of the anaesthetic. Bergamini uses a freshly prepared watery solution of novocain, its strength ranging from 0.10 to 0.15 per cent., with the addition of 1 mg. of adrenalin. About 50 to 100 c.cm. of the solution is generally sufficient for any operation, since it produces an anaesthesia which lasts about one and a half hours. About forty-five minutes before the operation 1 cg. of morphine is injected. Among 533 cases operated on at the Verona Hospital local anaesthesia alone was used in 62 per cent., and in association with general anaesthesia in another 11 per cent., so that in only 27 per cent. was general anaesthesia alone employed.

#### 476. Delayed Deaths following Chloroform Anaesthesia.

REICHEL (*Zentralbl. f. Chir.*, March 28th, 1925, p. 696) states that from 160 to 180 cases have been recorded in which a characteristic syndrome has developed after chloroform anaesthesia, always ending fatally in from one and a half to five days. The necropsy always shows very severe degeneration of the liver, with the appearance of acute yellow atrophy. A similar clinical picture and anatomical findings can be produced experimentally in animals by intoxication with chloroform. The occurrence of this syndrome is favoured by diseases which cause fatty degeneration of the liver, especially infective processes in the abdominal cavity. The condition has been most frequently observed hitherto after operation for acute appendicitis. Young persons, especially children, are most susceptible. The extreme rarity of this sequel, and the occurrence of several cases in one week, as was recently observed by Reichel, suggest that it is not pure chloroform but its decomposition products, or an impure chloroform, which are really responsible for these cases of intoxication. The practical conclusion to be drawn is that, in spite of its obvious advantages, the use of chloroform should be restricted as far as possible, since every bottle of chloroform cannot be examined before use. In children particularly, Reichel adds, the use of chloroform should be abandoned.

## Obstetrics and Gynaecology.

## 477. Indicaemia in Pregnancy.

J. A. VAN DONGEN (*Nederl. Tijdschr. v. Geneesk.*, February 14th, 1925, p. 738) reviews the literature and records the results of his examinations for indican in the blood of sixty women, who were grouped as follows: (1) Five were non-pregnant women, three of whom were suffering from mortr-rhagia and two from salpingitis. In the latter the indicaemia was above the physiological amount but below the upper limit of the normal (2.24 mg. per litre). (2) Seven were normal pregnant women in whom the blood was examined from a few days to four weeks before delivery. The average indican value among these was 1.46 mg. per litre, or below the average. (3) Twenty-one were normal puerperal women in whom the blood was examined on the first to third day after confinement. In only four cases was there an indican value of 3.2 mg. per litre; in all the others it was below the normal. There was thus no evidence of a physiological excess of indican in the blood as maintained by Rahsiinon. (4) Sixteen were cases of albuminuria and imminent or actual eclampsia. The indican value in these cases was mostly above the physiological quantity, but in only two was it above the upper limit of the normal. No connexion was found between the amount of indican in the blood on the one hand, and the quantity of albumin in the urine, the height of the blood pressure, and the number of eclamptic attacks on the other. The average indican value in this group was 1.89 mg. per litre. (5) Three were cases of other pregnancy intoxications—namely, dermatosis gravidarum, pernicious vomiting, and osteomalacia. In the first two cases the indican value was below the normal and in the third above it (3.2 mg. per litre). (6) Eight were puerperal cases with albuminuria or eclampsia. None of these patients had indican values above the upper limits of the normal and half had a physiological indicaemia.

## 478. Radium Treatment of Cervical Carcinoma.

E. VILLARD and L. MICHON (*Lyon Méd.*, February 15th, 1925, p. 181) conclude that in the present state of knowledge it is unjustifiable to supersede surgical treatment by radium. Radium therapy, they remark, still requires further investigation, and does not yet justify dogmatic statements. The advantages of choosing radium rather than surgical treatment are that it has a selective action on the neoplastic cell, a negligible mortality, and a relatively simple technique. Its disadvantages, they state, are that—(1) the absorption of necrotic tissue may cause grave toxic symptoms; (2) distant metastases may be stimulated; (3) certain normal tissue cells, especially those of the intestine, are not indifferent to radium emanations, and may be adversely affected; (4) the technique of the applications is as yet insufficiently established, and the present-day advocacy of large doses may be regarded as evidence that the good results formerly described were in some cases deceptive; (5) in a certain number of cases fistulas, phlebitis, or severe pain follow the treatment. Surgical treatment removes diseased tissues, instead of involving their resorption. It permits extirpation of metastases which are too distant to be dealt with by radium applications; the mortality is diminishing steadily, especially with the use of the Mikolicz drain. The authors add that statistical comparisons are apt to be fallacious, but if all but five-year cases be excluded the best results described (13 to 21 per cent. of cures) after radium treatment are inferior to those of surgical treatment (26 per cent. and upwards). They hold that at present all operable cases should be treated surgically, but state that when the limits of the cervical neoplasm cannot easily be passed in surgical extirpation radium is preferable to all other modes of treatment.

## 479. Bartholinitis during Pregnancy.

COMMANDEUR and GAUCHERAND (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, 1925, 2, p. 174) adduce evidence that the prognosis of suppuration in Bartholin's gland during pregnancy is less grave than has sometimes been asserted, with respect to the risks of abortion, premature labour, or post-partum infection. Out of 14 patients with Bartholinitis, of whom the oldest was aged 23, the tumor was incised in 9, and drained in the early or late months of gestation. Labour occurred at term in all cases. Neither in these patients nor in three in whom the inflammatory swelling ruptured during delivery were any grave febrile sequelae noted. Nevertheless the incision of the gland during pregnancy, and concede that operative or manipulative interference with delivery may increase the risk of infection after labour.

## Pathology.

## 480. Cytological Changes in Incubated Blood.

By incubating hanging drops of blood taken by a paraffined pipette either from the heart or from the peripheral circulation MARGARET R. LEWIS (*Amer. Journ. Path.*, January, 1925, p. 91) observed the transformation and growth of the leucocytes into macrophages, epithelioid cells, and giant cells in chick, mammalian, and human blood. So far as could be determined by following the cells in the incubated drops of blood, it seemed to the author that it was the mononuclear type that gave rise to the three kinds of transformed cells; granulocytes were not observed to become transformed. In every kind of blood examined there developed first a large wandering cell, several times larger than any of the normal leucocytes, which was phagocytic for red blood cells, melanin granules, carbon particles, dead granulocytes, and tubercle bacilli. Somewhat later there appeared a cell more like a primitive mesenchyme cell, and still later the epithelioid cell was formed. This cell was sometimes binucleate, and in some instances typical multinucleated giant cells (Langhans's giant cells) were formed. The author stresses the importance of the fact that there could be no possibility of participation in this phenomenon by the endothelium or the connective tissue. The hanging drops of human blood were made from blood taken from the finger. These were usually injured by contact with the glass, and while the cells often lived for two or three days and displayed the beginning of the transformation, they more frequently died before the formation of an epithelioid type of cell, unless the cover-glass was coated with some substance more favourable for their development. The best results were obtained by coating the covers with collodion. In some of these cultures of human blood the white blood cells lived for twenty days; in a few they lived nearly four weeks.

## 481. Carbohydrate Metabolism in the Placenta.

K. V. OETTINGEN (*Zentralbl. f. Gynäk.*, March 21st, 1925, p. 625) has found, in common with Liepmann, that if fresh placenta be perfused with 1 per cent. dextrose solution about one-quarter of the sugar disappears from the perfusing fluid. Since, however, the glycogen of the placenta does not become increased, and since the sugar undergoes a similar diminution during perfusion through a chemically poisoned placenta, it is concluded that the sugar is retained in the oedematous organ, and that the placenta possesses no special property of splitting the sugar molecule or of manufacturing glycogen. In another series of experiments insulin was added to the perfusing dextrose solution. The sugar was then found to be increased up to 10 per cent. This increase did not occur if the vital activity of the placenta had been destroyed and was not accompanied by a diminution of the placental glycogen. It is concluded that insulin possesses the property of increasing sugar catabolism in living tissues.

## 482. Urine Examination in Renal Tuberculosis.

R. GRANDINEAU (*Rev. Méd. de l'Est*, November, 1924, p. 726) contributes the results of urine examinations in a series of cases of renal tuberculosis. The method used was that of Ellermann and Erlundsen—namely, centrifuging, diluting the sediment with sodium carbonate, incubation for twenty-four hours at 37° C., centrifuging again, dilution of the sediment with sodium carbonate, boiling for a few minutes in a water-bath, centrifuging, fixing and staining a small drop of the sediment according to Spengler's method, prolonged treatment with Giell's stain being necessary. These preliminary measures are recompensed by the rapidity with which tubercle bacilli may be found on the slides. Examinations were made of bladder or kidney specimens, or both, kidney specimens being obtained when catheterizing of a ureter was necessitated. Catheter specimens were obtained when possible from the bladder, after careful cleansing of the meatus and the urethra to avoid contamination with the smegma bacillus. In cases where the bladder was irritable specimens passed in the ordinary way were collected during a period of several hours. Grandineau's cases fell into two groups: (1) Cases of calculus, hydronephrosis, etc., no clinical signs of renal tuberculosis being present. The organism was never found in these cases. (2) Definite cases of renal tuberculosis. Examination of bladder specimens alone gave 65 per cent. positive results; combined examination of bladder and kidney specimens resulted in 76 per cent. positive results. The author maintains that the direct examination of the urine for the tubercle bacillus in suspected renal tuberculosis should be a matter of routine, as it is in the case of the sputum in pulmonary disease.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### Duodenal Intubation.

463. LÉVY-DARRAS (*La vie médicale*, March 6th, 1925, p. 415) states that patients vary greatly in regard to tolerance of duodenal intubation; some swallow the metal bulb like a pill, while others may experience considerable initial discomfort. The patient's head and trunk should be inclined slightly backwards so that the olive-shaped metal bulb may glide downwards over the posterior pharyngeal wall. When 28 inches of the rubber tube has passed the incisor teeth, the bulb will have entered the stomach. The patient should then be turned towards the right side, when the weight of the bulb will carry it into the pylorus. Colourless acid gastric juice drips slowly from the end of the tube, but after an interval varying from thirty minutes to two hours this is replaced by viscid golden yellow alkaline bile, indicating that the duodenum has been reached. In doubtful cases this may be verified by causing the patient to drink a little water; if bile only is then aspirated from the tube it is evident that the bulb lies in the duodenum. The bile thus aspirated may be examined chemically and bacteriologically. The author considers the Meltzer-Lyon test very valuable and performs it as follows. By means of a syringe 30 c.c.m. of a 30 per cent. solution of magnesium sulphate in warm water is introduced into the duodenum. In normal subjects three successive specimens of bile can then be aspirated—(A) yellow bile from the bile ducts; (B) dark brown viscid bile from the gall bladder; and (C) yellow (hepatic) bile. The magnesium sulphate solution produces a contraction of the gall bladder and consequent evacuation of its bile. In the absence of the cystic duct, or pericholecystitis. Duodenal intubation also permits lavage or dila- tion, especially of the bile ducts. In gastric ulcer the patient may be fed by this channel. The sound may, Lévy-Darras finds, remain *in situ* for several weeks without danger.

### 464. Typhoid Septicaemia without Typhoid Ulcers.

W. FLETCHER and J. E. LESSLAR (*Indian Med. Gaz.*, January, 1925, p. 29) review the literature, including the recent cases of Zweig and Rehberg, and record the case of an old Chinese labourer suffering from a septicaemic condition from whose blood two strains of *B. typhosus* were isolated—the one smooth and agglutinable, the other rough and non-agglutinable. The serum agglutinated a stock emulsion of *B. typhosus* in high dilutions. *B. dysenteriae* Flexner, Type X, was isolated from the faeces on each of the four occasions when they were examined. The patient died about six weeks after the commencement of the illness. There was no marked thickening or inflammation of the gall bladder, but an agglutinable strain of *B. typhosus* was cultivated from it. There were two old pigmented scars just above the ileocaecal valve, but there were no typhoid ulcers. It was an open question whether the patient was a chronic carrier and the septicaemia the result of infection from an old focus in the gall bladder, or whether, on the contrary, the gall bladder had become recently infected as the result of the general septicaemia.

### Ocular and Vulvar Diphtheria.

465. CABANNES and GUINADEAU (*Gaz. hebdom. Sci. méd. de Bordeaux*, February 11th, 1925, p. 103), who record an illustrative case, state that ocular diphtheria is usually primary, and that it is exceptional to find it accompanying or following either forms of diphtheria, such as the naso-pharyngeal or laryngeal. Sordille has emphasized the frequency of ocular infection in streptococcal infection, which is relatively frequent to measles, and assumes a grave form owing to the rapid destruction of the eye and the frequency of a fatal termination. Association with staphylococci is the mildest form of concurrent infection. Many authorities regard bacteriological examination alone with suspicion, and Morax declares that he has seen only thirteen cases of undoubted ocular diphtheria, confirmed by inoculation of guinea-pigs, among 145,000 eye cases at the Hôpital Lariboisière in Paris. Cabannes and Guinaudeau, on the contrary, are of opinion that, though the number of cases at the Bordeaux sick children's hospital is considerably less, examples of ocular

diphtheria are relatively frequent, and the clinical and bacteriological signs are sufficient in themselves to render inoculation of guinea-pigs unnecessary. The present case was that of a girl, aged 3, who presented a profuse purulent yellowish discharge from the vulva with two membranous patches on the upper part of the labia majora. The left eye showed a superficial whitish membrane which was most marked in the upper conjunctival fornix. There was some chomosis round the cornea and palpebral oedema. The corresponding preauricular and submaxillary glands were enlarged and painful. The patient received intensive serum treatment, 100 c.c.m. being given on admission and 60 c.c.m. two days later. The affected eye was washed out twice daily with 1 in 10,000 solution of potassium permanganate, and drops of diphtheria antitoxin and argyrol were instilled. The vulvar lesions were treated with a sitz bath and a weak solution of potassium permanganate. Rapid improvement took place after the fourth day of treatment. Cultivation of the ocular membrane showed long diphtheria bacilli associated with staphylococci.

### Eosinophilia in Scarlet Fever.

466. Y. MARKOVITCH and M. GUERATOVITCH (*Presse Méd.*, February 14th, 1925, p. 205) studied the eosinophil cells in thirty cases of scarlet fever at the department for infectious diseases of the Belgrade Military Hospital, and came to the following conclusions: (1) The eosinophil reaction in scarlet fever depends on the clinical form of the disease. Eosinophilia is high and reaches its maximum in mild forms of uncomplicated scarlet fever. In severe and complicated forms eosinophilia is low during the acute stage and in the presence of complications, but as the general state improves there is a rise in the eosinophil curve. In septic forms which end fatally eosinophilia is absent or reduced to its normal level. (2) In obscure forms of scarlet fever eosinophilia is an important diagnostic sign, whether it be found at the onset or in the later stages of the disease. (3) In erythema scarlatiniforme the patient's good general condition and the normal number of eosinophils exclude a diagnosis of scarlet fever.

## Surgery.

### Surgical Treatment of Nephritis.

467. H. KÜMMELL (*Klin. Woch.*, March 5th, 1925, p. 439) describes various surgical operations that have been recommended in nephritis, including (1) nephrotomy, a very severe procedure, which has been largely superseded by (2) decapsulation; (3) nephrectomy, reserved for complete disorganization of the kidney; and (4) sympathectomy or neurectomy. Decapsulation is preferred on account of its relative simplicity and safety. Kümmell describes the immediate results following incision or the removal of the capsule, relief of pressure, and the restoration of the circulation and of the secreting function of the kidney. He states that unilateral decapsulation often relieves the congestion and restores the function of both kidneys; development of a new capsule occurs eventually, though more slowly in human patients than in animals. Ultimately a strong capsule is formed. Edema of the renal pelvis and perirenal vessels occurs frequently. In the exanthemata, and especially in scarlet fever, anuria and threatened anuria are especially in the third week of the disease and persisting for forty-eight hours was relieved by decapsulation, the renal function being restored for fourteen days. The patient, however, died later. Kümmell has performed decapsulation in 5 cases of mercuric chloride poisoning with anuria; one patient recovered. A woman who had taken oxalic acid recovered after decapsulation. In eclampsia, he adds, the operation has been remarkably successful. Sippel records 30 cures in 46 cases of decapsulation, and Poter has had over 60 recoveries in 98 cases. In acute infective (pyaemic) nephritis decapsulation has been very successful, especially in "nephritis apodematosus" with multiple (miliary) abscesses and pyelitis. Kümmell records 30 cases, the patients' ages ranging from 16 to 60; 27 patients recovered and 3 died. He reports a case of infective nephritis secondary to severe acute appendicitis in which decapsulation was performed after appendicectomy; the patient recovered. Chronic nephritis, both interstitial and granular, and interstitial nephritis without albuminuria but (in many cases) with perinephritis, pain, and paroxysmal haematuria, have been treated similarly

with satisfactory results. Out of 62 cases of the latter 53 were cured, 8 improved, 1 died. Of 56 patients with granular nephritis with albuminuria, hypertension, and, in most cases, very contracted kidneys, 24 were cured, 21 improved, 2 not improved, 9 died. In 24 with "nephrosis" 8 were cured, 9 improved, 4 unrelieved, 3 died. In glomerulo-nephritis, of 9 patients 4 were cured and 4 improved. Six patients with orthostatic albuminuria were cured. Of 33 patients with chronic nephritis treated by decapsulation—in 28 cases unilateral and in 5 cases bilateral—12 patients were cured, 8 improved, 3 not improved, 10 died. Among the patients who recovered, 2 remained cured after eighteen years, 1 after twelve years, 2 after five years; 2 patients died ten years after operation, but not from renal disease. Nine nephrotomies were performed: 5 patients were cured, 2 improved, 2 died. Kummell accepts Volhard's theory, that nephritis originates through "some universal arterial spasm," and remarks that the successful results of surgical treatment corroborate Volhard's views. He observes that the operation of decapsulation has not yet become popular, but he looks forward to the time when it will be as common an operation as appendicectomy.

#### 488. Adenoma of the Small Intestine.

J. A. VAN DIJK and A. J. F. OUBENDAL (*Nederl. Tijdschr. v. Geneesk.*, February 28th, 1925, p. 956), who record two illustrative cases, state that adenoma of the small intestine may give rise to a syndrome which may last for a long time, sometimes for years, consisting in sudden attacks at irregular intervals of intussusception, as manifested by symptoms of intestinal obstruction and the appearance of a rounded swelling. When an adenoma of the small intestine is found on laparotomy it is advisable to examine the whole of the small intestine for the presence of more of these growths. In two out of fifteen cases of adenoma of the small intestine collected by Wiedhoff more than one tumour was found in the same patient. In Zachary Cope's case laparotomy had to be performed five times and in Watt's case four times before the patient got rid of all his tumours. The authors' cases were in a brother and sister, aged 16 and 25 respectively, who showed a close physical resemblance to one another as well as similar pigmented marks on the mucous membrane of their lips. In the brother, in whom the adenoma was about the size of a cherry, an intussusception was found about 1 metre above the ileo-caecal valve. About 12 cm. of gut was resected and an end-to-end anastomosis performed. A second operation was necessitated by return of the symptoms three months later, when four adenomas were found and successfully removed. In the sister a tumour the size of a walnut was found about 50 cm. from the ileo-caecal valve; 15 cm. of gut was resected and an end-to-end anastomosis performed. Complete recovery took place. The naked-eye appearance, which was that of a polypus, and the histological structure of the growths were the same in the two cases.

#### 489. The Occurrence of Cancer in Mega-oesophagus.

J. REBATTU and C. PETOURAUD (*Arch. Internat. de Laryngol., Otol. et Rhinol.*, February, 1925, p. 151) state that there are usually no signs or symptoms in the early stages of mega-oesophagus (idiopathic dilatation of the oesophagus), and that this organ is profoundly changed before disturbances of function become obvious. Infective oesophagitis is a not uncommon complication and causes thickening of the walls. Another complication is the appearance of carcinoma in the dilated portion of the viscus; Fleiner puts the onset of cancer as one in fifteen cases of mega-oesophagus. The carcinomatous degeneration is explained in various ways. Dilatation may be followed by infection, and this hyaline-plakia (leucoplakic patches are often seen), which is a precancerous condition. It has also been suggested that certain cells may be included as an inherent part of the malformation and give rise to the cancer. Certain cases appear to be due to intramucine changes, infective rather than developmental. The cancer occurs more commonly in the middle third, but occasionally in the lower third, of the oesophagus. Unlike the ordinary type of cancer it is of very considerable extent, and occupied 12 and 15 cm. of the tube in two cases. In nine cases described the dilatation occurred throughout the tube and could not have been secondary to the cancer. Gnisez has shown that the dilatation following on cancerous conditions of the oesophagus is usually localized and of small extent. In some of the cases dilatation was definitely shown by x rays before there was any indication of malignant infiltration. The short period of survival of malignant patients after the onset of cancer contraindicated cancer being the cause of the extreme dilatation of the gullet, and in another had a diameter of 17 cm. The glandular involvement in the mediastinum is remarkably extensive:

great masses of glands round the oesophagus compress its lumen. Metastases appeared in the liver in a third of the cases. In several cases cancer cells were found in otherwise healthy mucosa at some distance from the main growth. This type of cancer appears usually in comparatively young people (aged 35 to 45) as compared with the ordinary oesophageal cancer. Of the nine cases described eight were male. Syphilis does not appear to be a particularly predisposing factor. The authors are much impressed by the latency of mega-oesophagus and by the extremely rapid progress of carcinoma in it, death occurring usually in a few months. Infection of the pleura and lungs is not uncommon, with abscess and gangrene.

## Therapeutics.

#### 490. Stovarsol in Protozoal Intestinal Infections.

PELZETAKIS (*Presse Méd.*, March 7th, 1925, p. 239) refers to Ravaut's introduction of intravenous injections of arsenobenzol as a remedy for amoebic infections. Several French authorities have obtained satisfactory results with stovarsol. Marchoux states that stovarsol cures amoebic dysentery speedily, but Pelzetakis cannot affirm this absolutely; he has had, however, very satisfactory results in lambliaias and trichomoniasis. He concludes that prolonged administration (oral) of stovarsol is needed to ensure a cure in dysentery, and that it cannot supersede intravenous injections of emetine. It is an excellent remedy for protozoal infections, and doses of 0.5 to 1 gram per diem (adult dose) are, he states, well borne usually. He claims that in infantile dysentery it is very useful, especially in cases in which emetine is not well tolerated. In lambliaias and trichomoniasis it is also very efficacious, and it appears to be valuable in the prophylaxis of amoebic dysentery.

#### 491. Treatment of Chronic Gonorrhoea.

H. SACHS (*Zentralbl. f. Gynäk.*, March 21st, 1925, p. 649) reports 84 per cent. of successful results in the treatment of chronic gonorrhoea by a combination of local applications with the use of a freshly prepared vaccine. The vaccine was made from six or eight strains of gonococci derived from acute cases, and was given intravenously in weekly doses of 1 c.c.m., containing 100 million organisms. The urethra received once or twice daily applications of 1 per cent. silver nitrate or other gonocidal preparations, and the cervix was treated from three to six times weekly with 5 per cent. silver nitrate. The average duration of treatment was three months, and complete bodily rest was regarded as an essential part of it; as a rule, six injections of vaccine sufficed. The cases refractory to this treatment included two of pregnancy and several in which there was evidence of infection of the body of the uterus; the successful cases included ten out of eleven of gonorrhoea in girls aged 14 or less.

#### 492. Vaccine Treatment of Rheumatic Myocarditis.

R. LAUTIER (*Bull. Soc. de Thér.*, February 12th, 1925, p. 69) has employed Bortrand's vaccine, prepared from Achalmé's bacillus, in the treatment of acute and chronic rheumatic myocarditis. The first dose contains 25 million bacilli. The second, which is given forty-eight hours after the first, 50 million bacilli; the third, which is given three days after the second, 75 million bacilli, and so on, each dose being increased by 25 million bacilli, and the interval between them being prolonged by one day. After the second injection the cardiac action becomes steady, the pulse normal, and the functional capacity of the myocardium is entirely restored without any other medication or regimen being required. All external and internal administration of salicyl preparations should be suspended, as they are incompatible with the antirheumatic vaccine. If salicylates have been employed, three days should elapse between their suspension and the institution of vaccine therapy. The vaccine treatment should be continued after apparent recovery and disappearance of all the symptoms owing to the liability of the rheumatic infection to relapse. The vaccine has no toxic action and can be administered over a long period without any ill effects.

#### 493. Treatment of Vincent's Angina.

J. LE GOFF (*Thèse de Paris*, 1925, No. 30) states that local antiseptics is the only treatment required for Vincent's angina. Removal of the primary cause of the bucco-pharyngeal infection, such as a wisdom tooth, is doubtless of importance but is a secondary consideration. Injections of "914" or other preparations should be reserved for very severe cases of bucco-pharyngeal infection, but are not devoid of risk. Three local

antiseptics are particularly useful in the treatment of Vincent's angina—namely, methylceno blue, arsonobenzol and its derivatives, and bismuth and its derivatives. Methylceno blue is an excellent antiseptic when the ulceration is not deep, and is a good means of curing mild forms of the affection. On the other hand, though it has a powerful action on the superficial spirilla, it has very little effect on those situated in the depth of the tissues, and is therefore inadequate in cases in which there is rapid sloughing. Arsonobenzol and bismuth and their derivatives, however, are spirillicides which are active at any depth, for their combinations with the tissues are spirillicidal. Bismuth preparations, though they do not clear up the ulcer so rapidly as arsonobenzol, relieve the pain more quickly, which is a distinct advantage. The author has employed bismuth in the form of 3 per cent. solution of neotropol in olive oil four times a day with good results.

## Diseases of Children.

394.

### Melaena Neonatorum.

ELLEN M. KENT HUGHES and N. E. DAVIS (*Med. Journ. of Australia*, March 7th, 1925, p. 238) report a case of melaena neonatorum in a female baby, 3 days old, the tenth child of a healthy woman. Notwithstanding treatment the loss of blood continued until the child became almost pulseless. The injection of 30 c.cm. of the father's blood into the buttock of the child was followed by cessation of the haemorrhage, which did not recur. With regard to the suggestion that haemorrhage in the newly born is due to some infective condition, the authors note that the mother had a severe attack of mumps during the eighth month of pregnancy, and tonsillitis during the ninth month; a week after her confinement she suffered from a breast abscess. All her previous pregnancies and confinements had been normal. At the age of 2½ months the child was still pale but was making good progress. On the same page A. J. M. PUNCHES reports a case of melaena in an apparently healthy male infant after forceps delivery, there being no evidence of disease of any kind in the mother. The child began to vomit blood thirty-six hours after birth and passed a large motion of pure blood. The haemorrhage continued and was unchecked by adrenalin or serum. The injection of 3 c.cm. of the mother's blood into the flank of the child stopped the bleeding immediately, and recovery, though slow, was continuous for four weeks.

395.

### Hospitalism in Children's Homes.

Z. ERIKSSON (*Acta Paediatrica*, Supplement, February 4th, 1925, p. 1), as the result of investigations in various children's homes at Malmö, came to the following conclusions: (1) Institution children are on the average physically inferior to proletariate children of the same age, as is most clearly seen in their retardation of growth in length and breadth. On the other hand, the increase in weight is delayed only in the younger children, and the growth of the skull is approximately normal. Institution children are mostly pale, flaccid, and less muscular than normal; their disposition is not so cheerful, their mental functions are late in development, and they are slow in acquiring habits of cleanliness. Their sleep, on the other hand, does not appear to be affected. (2) Institution children show a diminished resistance to a number of typical diseases of childhood, such as measles, diphtheria, pneumonia, and acute nutritional disorders, as is manifested by an increased mortality from these diseases. (3) The chief causes of hospitalism in infants is the frequency of infections, the pathogenicity of which is perhaps raised by an increased frequency of infections. Another factor is the frequency of rickets. The frequency of rickets is a cause and partly a consequence of hospitalism.

396.

### Congenital Measles.

J. A. MARIANI (*Thèse de Paris*, 1925, No. 45) states that congenital measles is rare in civilized countries for the following reasons: (1) The disease seldom occurs in adult women, most of whom have had measles in childhood or adolescence. (2) The child is rarely infected. Infection of the child occurs through the placenta, most probably during the period of invasion of the disease in the mother. If the child is born dead or dies shortly after birth it is impossible to say whether it has escaped infection or not. If pregnancy is not interrupted, and the child is born at full term without showing any signs of measles, it is impossible to prove an ante-natal infection. Nevertheless permanent immunity to measles in a child born under such conditions would be an argument in favour of intrauterine infection. If the eruption appears at

birth, or a few days later, the case is obviously one of congenital measles. In rare instances the mother has measles but the child is not infected. In such cases the child sometimes survives too short a time, or is too weak to react. In such circumstances no conclusion is justifiable. On the other hand, if the child is vigorous at birth and develops normally, without presenting any symptoms subsequently, the absence of infection may be asserted. There is no example on record of congenital measles without the disease being present in the mother, as may occur in the case of small-pox. Mariani adds that congenital measles is a serious disease, especially as the child in such cases is very often promaturo. Prophylaxis consists in infection of the mother, and later of the child, with convalescent measles serum, and enforcement of maternal nursing.

397.

### Surgical Treatment of Cleft Palate.

C. N. DOWD (*Annals of Surgery*, March, 1925, p. 573) estimating the incidence of cleft palate and hare-lip, finds that these defects occur once in 1,170 births, and formulates the following principles of treatment: Very early operation is desirable, and it should be performed in several stages; a cleft in the alveolar arch should be corrected before the bones have hardened; early repair of the lip causes useful pressure on the premaxilla; the flexibility and depth of the soft palate must be preserved with the utmost care. Dowd further advises that in restoring the palate iodoform gauze packing and supporting metal plates should be used. The packing supports the flaps and postpones their union to the palate bones; the metal plates, held by silver wire, support the flaps. These procedures greatly aid in obtaining firm union. The hard palate should be repaired a few months after the operation on the lip, and the operation on the soft palate should be postponed until the hard palate has united correctly. The author adds that the Langenbeck operation is generally used with certain modifications. The flaps are approximated with silver wire passed through aluminium plates; these give good support and rarely cause sloughing. The soft palate operation should be performed at the age of 12 or 18 months. Speech instruction should be begun early and continued persistently and carefully under skilful instruction. The problem of the nasal deformity is one of the most difficult, and various plastic operations have been tried. The loosening of the nasal attachment and pulling the ala forwards and to the mid-line by a wire may be helpful.

## Obstetrics and Gynaecology.

498.

### Aneurysm simulating Adnexal Tumour.

H. C. BRUNNEN (*Zentralbl. f. Gynäk.*, March 14th, 1925, p. 603) reports the case of a woman, aged 25, who after an abortion developed pyrexia and a very offensive discharge. The joints were painful and swollen, the temperature was 100° to 102.5°. She had had two previous attacks of articular rheumatism. Splenic swelling was discovered five weeks later, and there was a generalized blood infection. Subsequently she had a sudden severe attack of pain in the right inguinal region with a definite local swelling; this extended subsequently to the whole thigh. When admitted to hospital three weeks later she was very emaciated, anaemic, and slightly jaundiced. In the right hypogastric region there was a definite tumour extending to the umbilical level and to within half an inch of the median line. It filled the right iliac fossa and there was deep fluctuation. No splenic tumour was felt, but the inguinal lymph glands on either side were as large as hazel-nuts. Biannually, the uterus was found to be of normal size, as were the left adnexa. On the right side was a thick-walled tumour extending to the right uterine cornu, the right half of the pouch of Douglas, and the sacrum. No pulsation or thrill could be detected. The possibility of an adnexal abscess, a gravitation, or perilymphatic abscess was dismissed and the tumour considered most probable. The tumour was aspirated through the abdominal wall and dark fluid blood appeared; a second puncture through the posterior part of the vaginal fornix yielded similar drops of blood, and a diagnosis of haematocoele was made. The patient's condition precluded laparotomy, so the pouch of Douglas was opened with the thermocautery, when more than 500 c.cm. of arterial blood escaped. The haemorrhage was arrested by compression of the aorta; but in spite of saline transfusion the patient died in a few minutes. At the necropsy, a saccular aneurysm was found as large as a man's fist, commencing 3 cm. above the origin of the hypogastric from the common iliac artery. The sac was partly lined with organized clot. There was an old incomplete rupture over the psoas sheath which had probably occurred when the sudden attack of pain was felt.

The femoral artery was not involved, but there was complete thrombosis of the femoral vein. The mitral valve was the site of "verruccose" endocarditis, with considerable ventricular hypertrophy. In the spleen there was an embolic infarct.

#### 499. Severe Oedema of the Vulva during Pregnancy.

O. HOEHNE (*Deut. med. Woch.*, January 9th, 1925, p. 57) gives an account of five cases of severe oedema of the vulva complicating pregnancy at a late stage. He distrusts expectant and conservative treatment, as it may lead to spontaneous rupture of the tissues, which become infected and gangrenous. His first case, in which both mother and child died, gives point to this warning. In the second case Caesarean section was followed by the recovery of the mother and the survival of the child. In the third case also an extraperitoneal Caesarean section saved the lives of both mother and child, and an observation made during the operation gave the author a clue to the rational treatment of such cases. While he was incising the fascia above the symphysis much oedema fluid escaped from the wound in the abdominal wall, and by the time the operation was completed the swelling of the vulva was considerably reduced. Accordingly, in his fifth case, the author drained the vulva by a transverse incision to the right of and above the symphysis, the skin and the subcutaneous fat being divided for a distance of 6 cm. Oedema fluid escaped rapidly, and within half an hour the swelling of the vulva had almost completely disappeared. The wound was closed over a rubber drainage tube and the vulva firmly bandaged. The oedema disappeared completely in two days, and did not recur during the final stage of pregnancy. The patient went to term and was delivered of a live infant, weighing 7 lb. Hoehne asserts that an incision in the position indicated is much less likely to become infected than one carried over the vulva itself, and that it is unwise to wait until oedema of the vulva has impaired the vitality of the structures involved.

#### 500. The Sedimentation Test in Gynaecology.

NTSCHMANN (*Deut. med. Woch.*, March 6th, 1925, p. 393) has investigated the rate of sedimentation of the red corpuscles at the University Gynaecological Hospital in K8alsberg, where this test was performed about 600 times in about 200 gynaecological cases. As a rule, this test was supplemented by leucocyte and erythrocyte counts, and a determination of the percentage of haemoglobin. In forty-five cases of inflammatory processes it was found that when the condition was acute the rate of sedimentation was rapid, whereas when it was chronic this rate was normal or only slightly accelerated. The rate ran parallel with the extent of the disease and with the fever and leucocyte curves, but acceleration began before the temperature rose and leucocytosis was demonstrable, and it remained rapid after both fever and leucocytosis had disappeared. The rate of sedimentation would therefore seem to be the most delicate indicator of the three. With regard to the differential diagnosis of tubal pregnancy and diseases of the uterine appendages, it was observed that a normal, or only slightly accelerated, rate more commonly indicated an unruptured tubal pregnancy than inflammatory disease of the appendages. The test proved of little value in the diagnosis and prognosis of febrile abortions. The author considers this test of supplementary value; it should be used with the various other tests.

## Pathology.

#### 501. Transmission of Virus in Polio-encephalo-myelitis.

E. W. GOODPASTURE (*Amer. Journ. Path.*, January, 1925, p. 1) presents experimental evidence to show: (1) that within cells of early lesions experimentally induced in rabbits with herpetic virus there occur characteristic intranuclear inclusions; and (2) that the virus of herpes simplex reaches the central nervous system through the medium of nerves supplying the peripheral areas primarily inoculated. He suggests that a similar route is taken by the virus of human polio-encephalo-myelitis. The intranuclear inclusions were readily obtained by inoculating herpetic virus directly into a corpus luteum of early pregnancy. At the end of twenty-four hours the corpus luteum cells contained well developed inclusions, and the ovary was rich in virus. The herpetic bodies were acidophilic and distinct from nucleoli and chromatin. In the infected tissues the nucleus became enlarged, chromatin particles collected about the nuclear membrane, and an "inclusion" occupied the centre of the nuclear space, often separated from the nuclear membrane by a clear zone. Such intranuclear inclusions, the author suggests, correlate histologically the lesions of three human diseases—herpes simplex, herpes zoster, and varicella.

932 D

They occur in the cells of the cutaneous eruption of each of these infections and have not so far been found in any other human diseases. When a strongly neurotropic strain of the virus of herpes simplex was inoculated upon the scarified cornea of a rabbit it constantly induced herpetic ophthalmitis. The virus reached the central nervous system along the sensory division of the fifth cranial nerve, producing in that root on the side inoculated an acute local herpetic lesion which prosecuted the acidophilic intranuclear inclusions. The virus might also be conveyed along motor or sympathetic nerves, depending upon the innervation of the peripheral site inoculated. Thus, for example, following an injection of the virus into the muscles of the hind leg, an acute myelitis was produced in the lumbar portion of the spinal cord; if the virus was inoculated into an adrenal gland or an ovary an acute myelitis followed, reaching the spinal cord at the point where sympathetic fibres from these organs entered. In contact cases of herpetic ophthalmitis in rabbits the virus reached the central nervous system through the sensory division of the fifth and the ninth cranial nerves. Probably in every case there was an initial herpetic infection in the mucous membrane of the mouth, nose, or throat. Further, the author believes that transmission occurs along axis-cylinders, that the virus grows within the axis-cylinders, propagating itself in this way to their central termination, infecting there the highly susceptible cerebral tissue, and spreading within the brain in a similar fashion. The possibility of the passage of the virus of poliomyelitis, under experimental conditions, from the periphery along nerve fibres to the central nervous system has been demonstrated, the author points out, by the investigations of Floxner and Lewis, and of Levaditi and Laodoliner. A case of polio-encephalo-myelitis is described in a boy, in which medullary lesions were found which appeared to be directly related to the central distribution of the ninth and tenth cranial nerves. The author suggests that this virus may enter the brain through the peripheral nerves, and that the regular route of invasion of the central nervous system is by way of the nerves supplying the mucous membrane of the mouth, nose, and pharynx, as in contact infection with herpes.

#### 502. Glycrophosphates and Rickets.

V. KORENCHESKY and MARJORIE CARR (*Biochem. Journ.*, vol. xix, No. 1, p. 101) conducted 19 experiments on 20 litters containing altogether 148 rats, inspired by Grosser's finding that marked calcium retention occurred in rickets children when this element was introduced subcutaneously in the form of a glycrophosphate. It had previously been shown that a diet deficient in the fat-soluble factor produced rickets in puppies, rats, and pigs, and that an increase in the calcium content of such a diet did not cure this type of rickets. It was also known that human rickets cannot be cured by an increased ingestion of calcium salts. Kahlbaum's pre-war calcium glycrophosphate, containing 14.72 per cent. calcium and 11.34 per cent. phosphorus, was used in 3 per cent. solution, warmed to about 37° C.; 1 to 2 c.c. of this solution, according to the size of the animal, was injected slowly into the subcutaneous tissue four or five times a week, the place of injection being altered each time. Without all these precautions indurations and necroses were produced at the places of injection. These injections considerably increased the degree of calcification of the skeleton of rats kept on a diet deficient in the fat-soluble factor only. There was not, however, the same general improvement as would follow a course of cod-liver oil, for the water content of the bones of these rats was the same as or higher than that of the controls, and only in about 50 per cent. of the rats injected was a slight improvement in the rachitic changes in the skeleton found histologically. The authors suggest that there is a difference in the mechanisms of calcification induced to the skeleton of rats on a diet deficient in the fat-soluble factor by administration of calcium glycrophosphate and of cod-liver oil respectively.

#### 503. Estimation of Pepsin in Gastric Ulcer.

T. ALDAY and R. MENDEZ (*Arch. de med., cir. y esp.*, January 24th, 1925, p. 145) have employed Motte's method for estimating the amount of pepsin in the gastric juice of patients with gastric ulcer, and have always found values above 40 pepsin units. In some cases the units were as high as 100 or more. In patients with hyperchlorhydria without ulcer excess of pepsin was never found, but the number of units ranged from 20 to 40. The highest values were usually obtained in sixty to ninety minutes, the secretion of pepsin sometimes running parallel with that of hydrochloric acid and sometimes not. High pepsin values were found in gastric ulcer with stenosis of the pylorus in the fasting state. No general curve of acidity or pepsin values can be drawn up for patients with gastric ulcer, but this condition should be suspected when more than 40 pepsin units are obtained.

## Medicine.

### 504. Hepatic Lesions in Spirochaetosis Ictero-haemorrhagica.

V. VANNI (*Rif. med.*, March 16th, 1925, p. 244) records his observations on the changes in the liver in two cases of human spirochaetosis and in 100 guinea-pigs infected by the virus. Of the two human patients one was a heavy drinker who died of spirochaetosis ictero-haemorrhagica a few days after the appearance of the jaundice, while in the other the infection was of longer duration. In the first case the lesions were attributable partly to alcohol and partly to the super-added infection, inasmuch as there were diffuse fatty degeneration, cloudy swelling of the liver cells, especially in the central zones of the lobules, considerable increase of connective tissue, and numerous newly formed bile canaliculi. There was also much small-celled interstitial infiltration which was arranged in characteristic nodules consisting mainly of polymorphonuclear cells and lymphocytes. With special staining methods (Volpino, Giemsa) the spirochaetes could be clearly shown, especially within and round the nodules. In the second case there were no marked changes in the liver cells, but small lymphocytic nodules were present consisting of 10 to 15 elements each, and numerous patches of hyaline necrosis containing broken up and pyknotic nuclei, mostly arranged at the periphery, together with numerous spirochaetes, which were almost entirely absent in the rest of the tissue. In the guinea-pig the lesions were of a varied character, the inflammatory predominating over the degenerative. In some cases there were signs of stasis, represented by dilatation of the central vein of the lobule, and dilatation and engorgement of the portal capillaries. These lesions were often accompanied by cloudy swelling of the liver cells, especially in the central part of the lobule. Haemosiderosis was found, especially in those animals which died after a rapid infection with haemorrhages visible to the naked eye; in other cases it was exceptional. Infiltration with glycogen was a constant feature, being found in the form of small masses stained reddish-brown by Langhans's method. The inflammatory changes consisted in diffuse interstitial lymphocytic infiltration, often associated with the formation of millary nodules consisting of polymorphonuclear and mononuclear cells in the interior of the hepatic cells or in the neighbourhood of the central vein. The spirochaetes were grouped in and around these nodules.

### 505. Typhoid and Paratyphoid Thyroiditis.

P. J. A. L. ALAIN (*Thèses de Bordeaux*, 1924-25, No. 55), who records sixteen cases, one of which is original, states that 62 per cent. of patients with typhoid and paratyphoid thyroiditis had already had a goitre before their attack of enteric fever; 19 per cent. came from a country where goitre was endemic, and 19 per cent. had no previous thyroid history. In 75 per cent. thyroiditis occurred in convalescence from typhoid or paratyphoid fever, and in 25 per cent. a long time after the attacks—namely, nine years in one case and twenty-one years in another. In 55 per cent. of the cases a pure culture of *B. typhosus* was obtained, in 6 per cent. of *B. paratyphosus* A, in 13 per cent. of *B. paratyphosus* B, and in 19 per cent. of *B. typhosus* associated with another organism. In 6 per cent. the pus was sterile, and in 6 per cent. one part of the gland was sterile while the other contained virulent micro-organisms. Alain's case was in a girl, aged 15, who had had a goitre for a year. Inflammation of the right lobe of the thyroid developed in the fourth week of typhoid fever and suppuration took place, numerous typhoid bacilli being found in the pus. Signs of dysthyroidism such as tremors of the hands and slight exophthalmos were present. Complete recovery followed evacuation of the abscess.

### 506. Geographical Differences in the Character of Goitres.

J. HOLST (*Tidsskrift f. d. Norske Lægef.*, February 15th, 1925, p. 182) attaches great importance to the differences in the character of goitres in various countries, in some of which iodine therapy may, on the whole, be beneficial as a prophylactic measure, while in others it may do much harm. Even in neighbouring areas, such as Berne and Basle, there are definite morphological differences in the character of the goitres, and in Germany it is agreed that, while the goitres of the lowlands are as a rule small-noduled or diffuse, the goitres of the highlands tend to be large-noduled. There are also

functional as well as structural differences depending on geographical factors. Thus in Norway there is a tendency to hyperfunction and in Switzerland to hypofunction of the diseased thyroid. The Norwegian endemic goitre is often the precursor of a secondary thyrotoxic condition (secondary Graves's disease), whereas this sequence of events is practically unknown with the endemic Swiss goitre. The cases operated on by Kocher were either imported from abroad or were the results of iodine poisoning. Agalnia, cretinism is common in Switzerland, whereas the fully developed cretin is unknown in Norway, and half-cretins and quarter-cretins are very rare. In view of these differences, the author insists that, though iodine prophylaxis may, on the whole, be a wise measure in Switzerland where the endemic goitre is due to an imperfectly functioning structure, such medication in Norway may prove disastrous. Indeed, in Norway the complication of endemic goitre which most often renders the patient unfit for work or forces him to undergo an operation is not the mechanical action of the goitre nor the result of thyroid deficiency, but a secondary thyrotoxic condition, and this is very often provoked by iodine.

### 507. Epidemic Encephalitis in Holland.

L. BOUMAN (*Nederl. Tijdschr. v. Geneesk.*, February 21st, 1925, p. 853) has collected 189 cases of epidemic encephalitis in the acute stage during the period 1918-23 from Dutch literature, the distribution among children and adults being as follows:—Children: 1918, 1; 1919, 4; 1920, 6; 1921, 10; 1922, 6; 1923, 8. Adults: 1918, 7; 1919, 11; 1920, 49; 1921, 39; 1922, 22; 1923, 26. The residual forms amounted to a total of 151 cases, which were distributed as follows:—Children: 1918, 2; 1919, 3; 1920, 5; 1921, 5; 1922, 4; 1923, 7. Adults: 1918, 3; 1919, 1; 1920, 14; 1921, 25; 1922, 48; 1923, 33. During the acute stage the somnolent form predominated, being found in 65.7 per cent. of the cases. The hyperkinetic form occurred in 21.4 per cent., and in some cases was associated with the somnolent form. Occasionally very acute cases were observed, resembling rabies or epilepsy. In 93 cases Parkinsonism, and in 22 cases hyperkinetic conditions were noted among the residual forms. The mortality in the acute stage was reckoned at 27.5 per cent. In only two instances did a relapse occur.

## Surgery.

### 508. Sympathectomy for Epilepsy.

A. WAGNER (*Zentralbl. f. Chir.*, March 21st, 1925, p. 637) alludes to a case recently reported by Witzel of epileptiform convulsions following a gunshot wound of the motor area in which periarterial neurectomy of the carotid gland and excision of the superior cervical ganglion were performed. No further attacks occurred, but Wagner does not know whether this good result was permanent. He now reports a case in which he performed this operation for essential epilepsy on a woman, aged 65, who for the last twenty-five years had undergone every possible treatment without effect. The attacks at first became decidedly fewer and the mental condition improved for about three months. The attacks then became frequent again and progressive mental deterioration occurred. Microscopical examination of the superior cervical ganglion showed a remarkable pigmentation of the ganglion cells, but no inflammatory or degenerative changes. The initial improvement in this case induced Wagner to perform the operation on another woman, aged 24, whose attacks of epilepsy were much less severe. No appreciable change, however, resulted. Microscopical examination of the superior cervical ganglion in this case also showed an abnormal pigmentation of the ganglion cells. The author remarks that it would be interesting to learn, if this pigmentation of the superior cervical ganglion is a typical lesion of epilepsy, what is its significance.

### 509. Staphylococcal Meningitis.

DUPÉRIÉ, ROCHER, and AURIAT (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, March 10th, 1925, p. 260) record the case of a boy, aged 13, who showed symptoms of acute meningitis simultaneously with the development of signs of deep inflammation in the left lumbar region. Low lumbar puncture on the seventh day of the illness released purulent cerebro-spinal fluid containing *Staphylococcus aureus*. On the tenth day the signs of deep lumbar suppuration were

more definite, and resection of the left lamina of the second lumbar vertebra was performed. The bone was found to be deaused of periosteum and bathed in pus. After the resection the dural sac, distended with pus, was opened and drained. The patient's serious condition was further complicated by acute parotitis. An "iodized" autogenous vaccine was given by dural puncture every two days, and intradural injections of colloidal tin were administered *la largo doses*. As the meningitis appeared to shut off the lumbar region a farther resection of the laminae of the first and second lumbar vertebrae was performed, the dural cul-de-sac being incised to the extent of 3 cm. and drained. Pus and cerebrospinal fluid flowed into the dressings, and after a few days the meningial symptoms subsided. The patient recovered except for paralysis of the muscles of the antero-external part of the left leg, and this was improving after three months' electrical treatment.

#### 510. Strangulation of Epigastric Hernia.

L. MASSÉ (*Rev. de Chir.*, No. 2, 1925, p. 126) draws attention to the fact that epigastric hernias are not infrequently found to be irreducible, but that on the other hand it is extremely rare to find them strangulated. This frequent irreducibility is no doubt explained by the contents of the sac being usually omentum, which, as the result of attacks of inflammation, becomes fixed by adhesions. Epigastric hernias have been divided into four groups: (1) those which are simply fatty with no peritoneal sac; (2) fatty hernias with a sac containing omentum; (3) omental hernias without a fatty covering; (4) hernias containing omentum and bowel. The last group is the type least often encountered and which contains the cases liable to strangulation. An investigation of the literature confirms the infrequency of strangulation in this variety of hernia. Massé has collected fourteen cases recorded up to date. As regards the treatment of the condition, he states that it is necessary to relieve the strangulation and to perform a radical cure for the hernia. In these cases the patient's general condition is often poor and local anaesthesia may be advisable. The operative results, however, appear to be satisfactory, as there was only one case which proved fatal. In some cases it has been found necessary to use a filigree of bronze aluminium, and the results have been satisfactory, with no recurrence of the hernia up to date.

#### 511. Benign Gastric Tumours.

P. LECÈNE (*Paris Méd.*, April 4th, 1925, p. 313) states that gastric tumours may be classified into (1) adenomas of the gastric mucosa, single or multiple, sessile or pedunculated; (2) fibromas or lipomas arising usually in the submucous connective tissue; (3) leiomyomas originating in the unstripped muscle fibres; (4) neurofibromas, peripheral gliomas, or neurinomas—rare tumours formerly confused with sarcoma. Usually these tumours are only recognized clinically when they produce haemorrhages or mechanical disturbances due to pyloric obstruction. Lecène recommends that, whenever possible, a gastric tumour should be removed lest it become ulcerated by friction with the stomach walls and dangerous haemorrhages follow. He describes the case of a man, aged 30, who had a sudden attack of abdominal pain suggesting perforation of a gastric ulcer or acute peritonitis. Lecène explored the appendix region twenty hours after the onset and found a large quantity of fluid blood and clots. The appendix was not obviously diseased, and the cause of the intraperitoneal haemorrhage was not found, the patient's condition preventing any extensive exploration. The patient was radiographed after a bismuth meal and the stomach appeared deformed, elongated, and nodular; this was attributed to adhesions, but fourteen months after the operation the patient had severe and repeated melena and became very anaemic. Another skiagram then showed that the deformity was due to a tumour both exogastric and endogastric, and Lecène concluded that the blood came from an ulcer on a benign gastric tumour. The patient had no vomiting or haematemesis, nor could any tumour be felt on palpation. Three months later median laparotomy was performed and a nodular tumour was found in the posterior wall of the pyloric antrum adherent to the pancreas. A segment of the pylorus with the tumour was resected, but it was impossible to remove the other nodules, which were buried in the pancreas; they were evidently non-malignant. The parietal nodular tumour was as large as a mandarin orange with a central ulcer in the gastric mucosa of its inner surface; it was a leiomyoma. The diagnostic skiagram of the stomach recalled a similar case recorded in 1920 by Konjetzny (Kiel), who reported that at the pyloric antrum there was a clear, isolated, and almost circular patch which corresponded with a polypoid fibroma attached to the atrial wall. Lecène considers that such a radiological image is pathognomonic. He emphasizes the importance of determining the benignity of these tumours, which require simple excision only; extensive resection is quite unnecessary.

## Therapeutics.

#### 512. Insulin Treatment of Diabetes.

O. FISCHER (*Med. Klin.*, March 27th, 1925, p. 465) divides cases of diabetes mellitus into three groups, with respect to insulin treatment: (1) Cases in which insulin treatment is absolutely indicated, owing to immediate danger to life. (2) Cases in which, by dietetic treatment alone, the glycosuria cannot be checked, or only ceases when there is considerable undernutrition with acidosis (relative indication). (3) Cases in which a sufficient tolerance can be obtained by the usual dietetic treatment; these require no insulin treatment. In the first group are cases of coma and precomatose conditions. Here insulin should be given in large doses—the author recommends a subcutaneous injection of 50 units. The full effect occurs in three or four hours. If the symptoms have not subsided then, a second and similar dose is given, and this is repeated every three or four hours until the symptoms and the glycosuria are checked and the blood sugar is normal. Usually 100 to 150 units is required altogether. Fischer thinks that repeated blood sugar estimations are not necessary, repeated examinations of the urine being sufficient; so long as a positive reaction with Trommer's test is obtained the blood sugar is over 0.1 per cent. Together with the insulin administration 10 to 15 grams of sugar (saccharose) is given by the mouth thirty to sixty minutes after each injection, if the patient can swallow; in the most severe cases an intravenous injection of grape sugar is given. Strophanthin or digitalisat is also recommended. Three cases are recorded in detail. In two all the symptoms except slight acidosis were checked in twelve hours by 100 units of insulin. In another case the symptoms of coma were checked by insulin, but five days later death occurred from sepsis due to a carbuncle of the neck. Of fifteen patients with diabetic coma treated with insulin only one died, and in this case the treatment was commenced late. One of the patients was rescued from coma twice, and another three; three of the patients are still alive. Fischer states that in the great majority of cases coma was checked by vigorous insulin treatment, but the fate of the patients is little changed unless they remain permanently under careful treatment; finally the disease will prove fatal. He adds that insulin treatment is also of service when an operation is suddenly required in a case of diabetes, and time cannot be allowed for checking the glycosuria.

#### 513. Regulation of Insulin Dosage.

L. JONAS, T. G. MILLER, and IDA TELLER (*Arch. Intern. Med.*, March 15th, 1925, p. 289) record the results of a study of blood sugar curves in 6 non-diabetic and 25 diabetic individuals. These investigations were made in order to determine a more satisfactory method for the administration of insulin. The authors find that with a maintenance diet, equally distributed among the three meals of the day, mild cases of diabetes may be kept within the normal limits of glycaemia by means of a single dose of insulin half an hour before breakfast. More severe cases require also a second dose half an hour before the evening meal; and if these are insufficient a third one at midnight is indicated. When insulin is not being given (the diet factors being the same for each of the three meals) the highest blood sugar concentration was found to occur usually about one hour after breakfast, and the lowest before breakfast. In the study of diabetic patients the authors advise that three blood sugar determinations should be made: one on a specimen taken before breakfast or before the first dose of insulin, one an hour after breakfast, and a final one just before luncheon. In all cases of diabetes the single specimen of urine which is most likely to show sugar is one passed from one to two hours after breakfast.

#### 514. Insulin in General Practice.

R. FITZ (*Boston Med. and Surg. Journ.*, March 19th, 1925, p. 519), considering the possibilities of insulin in general practice, thinks that many of the patients now being sent to hospital for treatment could be as efficiently and more economically dealt with as out-patients or by their local practitioner. Since diabetes is often mild, only about one-third of the patients will require insulin, which is usually indicated only in undernourished young diabetics and those with surgical complications, acidosis, or an acute infection. Insulin rapidly reduces the sugar, and selected cases can be intensively treated satisfactorily in a few hours instead of days or weeks; patients can easily be taught to adjust their diets, to test for sugar, and to administer insulin. Fitz considers that a diagnosis of diabetic coma is justified only in the presence of glycosuria and acidosis. The importance of

early treatment of coma by large doses of insulin, plenty of fluid, and good nursing is urged, and in the absence of a marked infection, shock, or a very high blood sugar concentration, the prognosis is good.

## Neurology and Psychology.

### 515. Neuritis and Pseudo-tabes after Arsenobenzol Infections.

SÉZARY and CHABANIER (*Bull. et Mém. Soc. Hép. de Paris*, February 26th, 1925, p. 279) draw attention to the frequency of neuritis following arsenobenzol treatment, and report in detail several cases. In its early stages the condition resembles that of incipient tabes, as Sicard has shown, but the differential diagnosis is not difficult. The authors have seen two cases of a generalized sensory type, accompanied by ataxia, and resembling the polyneuritic tabes of Leval-piquet. Sézary and Chabanier divide their cases into two classes according to whether there is present a slight sensory neuritis with early pseudo-tabes, or, on the other hand, a generalized sensory neuritis with ataxic pseudo-tabes. One of their cases in the first group occurred in a man, aged 58, who had contracted syphilis when 31, but had had very little treatment. The Wassermann reaction was positive, and the patellar and tendo Achillis reflexes were normal in 1922. During the next two years he received many courses of treatment with arsenobenzol preparations, but the Wassermann reaction remained almost persistently positive. After the first course of "éparséno" he complained of painful tingling in the feet, and in 1924 it was found that the left patellar reflex had disappeared. Pain was felt in the left toe when the foot was placed on the ground; there was anesthesia of the end of the toe and the nail was much thickened, but there was no evidence of tabes or alcoholism, and the cerebro-spinal fluid was normal. This painful tingling in the toes and legs was characteristic of the other cases reported. The second group was illustrated by two cases, one being that of a research chemist, aged 45, who had not contracted syphilis, but had been engaged for three years in the commercial manufacture of arsenobenzol. Arsenical pigmentation of the skin was so intense that the patient was believed to be suffering from Addison's disease. Palmar and plantar hyperkeratosis existed, the gait was uncertain, and there was difficulty in stooping when the eyes were closed; the pupil reflexes were normal. Sézary and Chabanier remark that these cases indicate the possibility of a definite arsenical neuritis occurring when large doses of arsenobenzol are administered for a long time, though individual idiosyncrasy is an important factor. Patients usually recover when the injections are discontinued, and this is a further proof that the ataxia is non-syphilitic. Sicard has pointed out also that for a long period after recovery the tendo Achillis reflex may be absent. The authors add that in any doubtful case a lumbar puncture should be performed, since a normal cerebro-spinal fluid will indicate that the tabetic symptoms are not of syphilitic origin.

### 516. Innervation of Micturition.

F. J. F. BARRINGTON (*Quart. Journ. Exper. Physiol.*, March, 1925, p. 81), as the result of experimental work, has shown that the innervation of the process of micturition in the cat is not solely effected through the spinal cord. Destruction of a region ventral to the internal edge of the superior cerebellar peduncle, from the anterior end of the hind-brain in front to the level of the middle of the motor nucleus of the fifth nerve behind, is followed by permanent inability to empty the bladder if the lesion is bilateral, but not when it is unilateral. Bilateral destruction of the mid-brain from the ventral half of the side of the posterior end of the aqueduct onwards to just beyond the mesencephalic root of the fifth nerve is followed by a permanent loss of consciousness of the need to micturate or defecate, but does not impair the performance of either of these functions. A similar but rather more extensive lesion produces frequency of micturition in addition to the other results.

### 517. Morbid Anatomy of Schizophrenia.

M. PRADOS Y SUCH (*Arch. de med., cir. y esp.*, February 21st, 1925, p. 392) states that the morbid anatomy of schizophrenia is one of the most complicated and least settled problems of the histopathology of the nervous system. Macroscopically no important changes are observed. The lesions are always of a microscopical and parenchymatous character, and may be grouped under the following types: fatty degeneration of the nerve cell with various cellular changes, principally of a sclerotic nature, and changes in the arrangement of the cells in a large number of cases, but not frequent enough to justify the conclusion that schizophrenia is a systematized disease.

The neuroglia shows progressive and retrogressive changes, while the myelin and nerve fibres do not appear to be much affected, especially in recent cases. In no instance was there any sign of the mesodermic elements being affected. As regards the topographical distribution the cornu ammonis is one of the sites of predilection, and in the rest of the cortex the frontal lobe is most frequently involved. Numerous observers, however, have reported cases in which degenerated cells were found in all regions of the brain. Prados y Such has seen them in the basal ganglia, optic thalamus, and medulla oblongata. As regards involvement of the endocrine glands considerable disagreement prevails among the various observers, although the sexual glands appear to be most frequently attacked. Mott has described important changes in the testes and ovaries in the form of complete absence of spermatogenesis, sclerosis of the ovaries, and diminution or complete absence of the ovarian follicles. In conclusion the author maintains that in the present state of our knowledge it is impossible to establish the anatomical diagnosis of the disease with certainty, but only with some degree of probability.

## Obstetrics and Gynaecology.

### 518. Vulvo-vaginitis and Balano-posthitis Oïdo-mycotica as a Conjugal Infection.

T. BENEDEK (*Dermat. Woch.*, March 21st, 1925, p. 435) states that *Oidium albicans* has long been known to be a parasite of the genital mucous membrane, though comparatively few cases have been recorded of isolated involvement of the genitals by this organism. Still rarer are the cases in which both husband and wife become infected. Haumann in 1876 was the first to describe the presence in the vagina of *Oidium albicans*, which he successfully inoculated from the mouth of an infant with thrush. One of the earliest cases of isolated involvement of the vulva by *Oidium albicans* was reported by Giulini (*Zentralbl. f. Gyn.*, 1891, p. 1049). The rarity of the affection is shown by the fact that in the course of six years von Herff saw only 24 examples of acute and subacute colpitis oïdo-mycotica among 15,283 women at the Halle Gynaecological Polyclinic; 20 of these occurred in the summer and only 4 in the winter, whilst 15 were in pregnant women. No case was reported as occurring in virgins or after the climacteric. There is usually a special predisposition to infection by *Oidium albicans* in the form of general cachexia or some systemic disease, especially diabetes mellitus. Benedek records a case in an otherwise healthy and vigorous married woman, aged 28, in whom the internal aspect of the labia majora, labia minora, clitoris, and introitus vaginalis presented a dry greyish appearance without membranous formation, while the vagina showed a greyish-white loosely attached deposit on the columnar ring and in the intervening spaces. The symptoms were burning, itching, vaginal discharge, and greatly increased sexual appetite. The husband, a well developed healthy man, aged 32, a few days after sexual congress developed a greyish membrane on the inner surface of the prepuce, corona, and glans. The lesions in the wife cleared up in a few days after swabbing with a 10 per cent. solution of silver nitrate, and the husband's lesions were rapidly cured by the application of a 2 per cent. resorcin ointment. *Oidium albicans* was recovered from the genital lesions of both husband and wife.

### 519. Treatment of Febrile Abortions and Puerperal Fever.

H. KÜSTNER (*Dent. woch.*, February 6th, 1925, p. 223) discusses the principles adopted at the University Maternity Hospital at Halle in the treatment of abortions and puerperal fever. When an abortion is febrile he considers the only right course is to evacuate the uterus completely and at once, so that there shall be no dead matter within the uterus to afford pabulum to streptococci, whose virulence is apt to increase rapidly under such favourable conditions. When an abortion is febrile and incomplete he gives subcutaneous injections of gynergen, a tartrate preparation of ergot, at intervals of one to two hours, beginning with a dose of 0.2 c.cm. and gradually increasing the dose to 1 c.cm. In abortions from the third to the fifth month he has found that gynergen stimulates the uterus to contract more effectively than other drugs, such as ergot and pituitary extract. Within a few hours of starting this treatment the foetus is expelled, in many cases with the placenta. Even when spontaneous expulsion of the ovum was incomplete, and it was necessary to evacuate the uterus with a finger or instrument, injections of gynergen were helpful. Küstner thinks that it is better to evacuate the uterus at once under a general anaesthetic than to incur the delay entailed by spending twenty-four hours in dilating the cervix with laminaria, for in the interval streptococci already present in the uterus may have grown

more virulent and penetrated to the deeper structures of the uterus. He adds that injections of gynergen are also useful in stimulating the uterus to contract after a normal confinement at term, and that no ill effects have followed its employment. He has found a mixture of mercury perchloride and neosalvarsan beneficial in febrile abortions and puerperal fever. The mixture consists of 0.3 gram of neosalvarsan in 8 c.cm. of sterile water and 2 c.cm. of a 1 per cent. solution of mercury perchloride. This mixture, in which there is a black precipitate from the interaction of the two drugs, is given by intravenous injection, great care being taken to avoid necrosis of the tissues, which may follow the depositing of even a little of the fluid outside a vein. Even in those cases in which there had been several rigors before admission to hospital good results were obtained with this treatment, the efficacy of which was, however, greatest when it was started early. Its effect on the pulse was more rapid than on the temperature, a weak and very rapid pulse soon becoming stronger and slower.

#### 520. Cystoscopy in Cancer of the Cervix.

R. GOUVERNEUR and S. FABRE (*Gynéc. et Obstét.*, 1925, xi, 3, p. 189) have made cystoscopic observations in 200 cases of cancer of the cervix before and after radium treatment. In about one-third of the cases in which the bladder wall had been extensively invaded they found urinary signs and symptoms absent or extremely insignificant, and in a considerable minority of cases frequency of micturition was noted when the bladder wall was free. They conclude, therefore, that cystoscopy is of great value in estimating the operability of different cases. In this series only about 6 per cent. of cases showed neoplastic ulceration of the bladder, usually superficial and in the neighbourhood of the trigone. The other morbid appearances were due chiefly to distortion by the tumour and to inflammatory conditions in the line of its advance; bulging, oedema, and the formation of transverse folds are the chief appearances described. The detection of vesical ulceration is, they think, a grave prognostic sign, contraindicating curative radium therapy, but in such cases small doses such as 30 millicuries for three days were not followed by fistula formation. In cases which clinically seem cured after radium applications, the authors have found that little or no alteration ensues in the cystoscopic appearances of oedema or transverse corrugation.

## Pathology.

#### 521. Combination of Diphtheria Toxin with Living Tissues.

A. T. GLENNY and BARBARA E. HOPKINS (*Journ. Path. and Bact.*, April, 1925, p. 261) have tried to determine the rate at which diphtheria toxin is fixed by the tissues. They first measured the time that must elapse after the intradermal injection of a given dose of toxin into a guinea-pig in order to render ineffective a subsequent intravenous injection of antitoxin. Using a Schick dose of toxin injected into the skin, it was found that not even 10 units of antitoxin—an amount containing 10,000 times the equivalent of the toxin—given intravenously fifteen minutes later, was sufficient to prevent the appearance of a small reaction. If the interval between the injection of the toxin and the injection of the antitoxin was lengthened to three hours there was no neutralization and the normal reaction was produced; in this experiment the amount of antitoxin used was 1,000 units, or an equivalent of 1 million combining doses. The extent of the skin reaction produced by a Schick dose of toxin, when followed by certain doses of antitoxin, was then determined. Varying the size of the dose of toxin, the authors found that the smaller the amount injected, the greater was the proportion fixed in a given time. Thus, whereas only 20 per cent. of the full Schick dose was fixed within three hours, as much as 50 per cent. of a one-tenth Schick dose was fixed in this time. One important point brought out was the difference in the rate of absorption of antitoxin by different routes. Thus, to reduce by one-half the skin reaction caused by a Schick dose of toxin, it was necessary to inject 1,000 units of antitoxin intravenously one and a half hours later, intramuscularly three-quarters of an hour later, or subcutaneously a quarter of an hour earlier. The second method employed for estimating the rate of fixation of toxin was to inject a Schick dose of toxin intracutaneously and a variable dose of antitoxin intravenously some time afterwards, and to measure the amount of antitoxin formed by the animal. In this way it was found that even 1,000 units of antitoxin given three hours later was insufficient to prevent a rise in the antitoxic titre of the serum due to the antigenic effect of the toxin.

#### 522. The Multiplicity of Strains of the Bacteriophage.

E. WOLLMAN and ELISABETH WOLLMAN (*C. R. Soc. de Biologie*, March 7th, 1925, p. 552) possess a strain of anti-Shiga bacteriophage which is sensitive to the action of trypsin; when this ferment is added to it the bacteriophage loses its ability to form plaques on an agar culture of the dysenteriae bacillus. They have also an anti-coli bacteriophage which does not manifest this sensitivity. When equal parts of lytic filtrate and a 1 in 200 solution of trypsin were mixed together and incubated for a day or two the bacteriophage retained its activity completely. Is this difference in regard to trypsin between the two strains dependent upon the bacteriophage itself, or is it a function of the bacterium on which it flourishes? To answer this question they performed the following experiment. A tube of broth was inoculated with *B. dysenteriae* Shiga and a few drops of anti-coli bacteriophage added to it; another tube was inoculated with *B. coli* and a few drops of anti-Shiga bacteriophage added to it. On the next day the two tubes were heated at 60° C. for one hour; some drops from tube 1 were added to a fresh culture of Shiga's bacillus, and some drops of tube 2 to a fresh culture of *B. coli*. This was repeated several times. The result was that the anti-coli bacteriophage, which attacked the Shiga bacillus at the start, became more actively lytic during the successive passages on this organism; the anti-Shiga bacteriophage, which had no action on *B. coli* at the start, gradually acquired a lytic power, which after seven passages was as strong as in the case of its homologous bacillus. When the effect of trypsin on these two strains was tested it was found to be unaltered—that is to say, that neither the adaptation of the anti-coli bacteriophage to the Shiga bacillus nor the adaptation of the anti-Shiga bacteriophage to *B. coli* had altered in any way their susceptibility to the action of trypsin. These facts appear to the authors to be incompatible with the hypothesis which regards the bacteriophage as a product—ferment or pro-enzyme—of the bacillus with which it is associated; in this case, they think, its sensitivity to trypsin should vary with the organism it attacks. This, however, is not so; on the contrary, it appears that each strain of bacteriophage is endowed with certain properties, such as the sensitivity to trypsin, which remain constant during passage on different organisms, whereas other properties, such as the lytic power, are variable.

#### 523. Glandular Puncture in Bubonic Plague.

The usual method of diagnosis in suspected cases of bubonic plague is examination of the fluid aspirated from an enlarged gland. Satisfactory though this may be in the acute stage of the disease, it is, according to L. URIARTE (*C. R. Soc. de Biologie*, March 27th, 1925, p. 901), by no means a trustworthy procedure in the mild or chronic cases. In the former type the puncture is easy to perform, and the juice which is aspirated contains the bacilli in large numbers; but in the latter type, when the glands are hard and small, the process of puncturing is often very painful, and is not always attended by success—that is, no fluid is withdrawn. To avoid this it is advisable to inject a few drops of sterile saline and to suck this up and down within the gland. Even when this method is employed the examination of the tissue juices may fail to reveal the presence of the plague bacillus; in such cases it is difficult to give a definite diagnosis. To ascertain how many of these cases are really plague infections the author examined seven patients in whom simple ganglionic puncture had failed to reveal the plague bacillus. The glands were removed from the groin, cut up with care, inoculated on culture media, and injected into guinea-pigs. In three of them the *B. pestis* was grown in culture, and in the same three the injected animals died of plague. Later, another ten cases were similarly examined; two of them were proved by culture and by minute inoculation to be cases of plague, and one of tuberculosis. Uriarte concludes that it is clear that ganglionic puncture is an uncertain method of diagnosis in all but acute cases of plague, and that it should be replaced where necessary by excision of the gland, and also by a blood culture.

#### 524. Vitamins and Bactericidal Action of Blood.

G. M. FINDLAY and I. MACLEAN (*Biochem. Journ.*, vol. xix, No. 1, p. 63) have found that rats fed on a diet deficient in vitamin A and the antirachitic factor show a reduction in the bactericidal power of the blood only after the onset of keratomalacia or some other infection. Exposure to ultraviolet light during such deficient feeding delayed the onset of bacterial infection and the reduction in the bactericidal power of the blood. When keratomalacia had appeared exposure to ultraviolet light produced no effect. A diet lacking phosphorus and the antirachitic factor, or lacking vitamin B, also produced a reduction in the bactericidal power of the blood.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 525. Measles Treated by the Serum of Convalescents.

F. WULFF (*Ugeskrift for Læger*, April 9th, 1925, p. 369) gives an account of numerous experiments conducted in the Blegdams Fever Hospital in Copenhagen. When a child developed a measles rash other children in the ward who had not previously contracted measles were given an intramuscular injection of a mixed serum obtained from patients convalescent from measles. On the first occasion each of the children exposed to infection was given an injection of only 5 c.cm. of filtered serum. Three of them developed measles. On the second occasion, when measles developed in a child in a ward with five other children, the dosage of the serum was increased, 10 c.cm. being given to the youngest child (only 2 months old) and 20 c.cm. to the older children. None of them developed measles, although the potential source of infection was not isolated. On four other occasions the outbreak of measles was the signal for giving prophylactic injection of serum to "contacts." Summarizing his experiences on these six occasions, the author claims that the serum of convalescents is capable of aborting measles in the incubation period. He finds it difficult to determine the minimum effective dose, as it is probable that both the potency of the serum and the reaction of the patients to it vary considerably. The dosage which he adopts for the present is 5 c.cm. for infants under 1 year, 10 c.cm. for children from 1 to 4 years old, and 15 c.cm. for children over 4 years. He prefers unfiltered to filtered serum because filtration implies the loss of a considerable portion of the serum, and because, according to Degkwitz, the potency of filtered serum is less than that of unfiltered serum.

### 526. Prophylaxis of Whooping-cough.

V. GILLOT (*Bull. Acad. de Méd.*, February 10th, 1925, p. 176) holds that while the prophylaxis of whooping-cough by injection of the serum of convalescents is a well recognized method, it cannot be frequently employed owing to the difficulties involved in obtaining the serum and preparing it for use. On this account he has had recourse to a new and very simple method which can be carried out by any practitioner. It consists in subcutaneous injection of whole blood into children who have been exposed to infection. The blood may be taken from a person who has had whooping-cough at some time in his life, or from one of the parents without troubling to inquire if they have had whooping-cough or not. During a severe epidemic of pertussis at Algiers in 1924 Gillet employed this method at the children's clinic with the following results: (1) All the children who were injected before the period of invasion were effectively protected against the disease. (2) Those who were first injected at the onset had only very mild attacks. Only one injection was given, the dose ranging from 2 to 5 c.cm.

### 527. Hodgkin's Disease.

C. STERNBERG (*Klin. Woch.*, March 19th, 1925, p. 529) describes an anatomy of Hodgkin's disease, or considers that the histological pathognomonic, in whatever organs they are found. They consist of granulation tissue rich in cells, in which, between lymphocytes, plasma cells, and leucocytes, lie the characteristic large cells, with one or several large, round, indented or lobulated, darkly stained nuclei; and abundant protoplasm, which is often connected with the connective tissue stroma. The tissue is never composed of these large cells alone; they are intimately mixed with the other forms of cells, and in many cases a large number of eosinophilic leucocytes are present. Examination of the blood, though not conclusive, serves to exclude some other diseases. A high degree of eosinophilia is often found. A peculiar feature is the temperature, periods of thirteen to twenty days of fever alternating with fever-free intervals of varying duration. The disease usually ends fatally within five years; but under x-ray treatment the symptoms may subside and life may be prolonged up to ten years. From the clinical features a diagnosis can be made with great probability. It is made certain by the histological examination of an excised gland when the material is suitable. Sternberg adds that it is now almost generally acknowledged that the affection is a chronic inflammatory process, associated with the development of a peculiar granulation tissue, localized chiefly in lymphatic tissue, and characterized by large cells. He previously put forward the view that the

affection was caused by the tubercle bacillus, but he leaves the question open whether the peculiar histological changes are due to a special reaction, perhaps an increase in the resistance of the organism, or to a diminished virulence of the bacilli. He records the opinions of other observers for and against his view, but considers that the results of more recent observations and experiments appear to be increasingly in its favour.

### 529. The Diet in Typhoid Fever.

V. J. KINSELLA (*Med. Journ. of Australia*, February 21st, 1925, p. 183), in a paper based on the study of 760 typhoid patients treated at the Royal Prince Alfred Hospital, New South Wales, during the last thirteen years, comes to the following conclusions: (1) The old strict diet is deficient in caloric requirements. Such diet consists of a feed every two hours of prepared peptonized or elctrated milk, or whey and albumin water, each feed varying from 2 to 5 fluid ounces. (2) It results in severe wasting in prolonged infections. (3) During convalescence the hunger becomes ravenous. (4) With a diet of adequate caloric value extreme wasting and hunger are not seen. Such a diet consists of 2 pints of milk, 6 ounces of cream, 4 ounces of sugar, 3 or 4 eggs (in flaps, custards, or boiled), 2 ounces of fish, 4 ounces of bread, and 2 ounces of butter, amounting approximately to 3,000 calories. (5) Feasible on a liberal diet (11.5 per cent.) those on a restricted diet (11.6 per cent.) such as haemorrhage and perforation were not more frequent among those on a liberal diet. (7) In spite of the anorexia so common in enteric fever, the 2,000 to 3,000 calories mark is easily reached.

## Surgery.

### 529. Complications of Megacolon.

M. DERRAUX (*Bull. et Mém. Soc. Nat. de Chir.*, March 28th, 1925, p. 356) records two cases of megacolon complicated by intestinal obstruction. In the first, a girl aged 20, who was a vegetarian with a very large appetite, there had been no action of the bowels for seven days. Abdominal exploration showed that the condition was due to a volvulus of the descending colon. The bowel, which appeared to be in good condition, was untwisted and the abdomen closed. The patient made a satisfactory recovery. The second case occurred in a female, aged 35, who had been treated some years previously for symptoms of gastric ulcer with haematemesis and melaena and had been cured by medical means. She had an attack of acute obstruction with distension and severe pain, and, on laparotomy, the large and small gut were found very distended. Careful examination showed that the descending colon, which had a long mesentery, had passed through an opening in the transverse mesocolon. After puncturing the gut the hernia was reduced and the opening in the mesocolon closed, the patient making a good recovery. Derraux thinks that it seems advisable, in view of the complications to which cases of megacolon are liable, that a radical operation should be performed at a later date to prevent their recurrence. He adds that the primary condition is probably of congenital origin, but it is not improbably aggravated by a vegetarian diet and a diet rich in carbohydrate matter.

### 530. The Stomach as a Content of Inguinal Hernia.

J. DRESEN (*Zentralbl. f. Chir.*, February 28th, 1925, p. 457), who records a case of a stomach in the sac of an inguinal hernia, states that the presence of abdominal organs in the hernial sac is an everyday occurrence. According to Kessler's statistics of the Bonn University Clinic (Inang. Diss., Bonn, 1923) the appendix alone was found in 1.09 per cent., the cecum and appendix in 0.72 per cent., and the appendix with other parts of the intestine in 1.37 per cent. The transverse colon, sigmoid, jejunum, and ileum with the mesentery, uterus and oviducts, bladder and omentum are relatively frequently found in the hernial sac. There are only twelve cases, however, on record in which the stomach was found in the sac of an inguinal hernia. In one of these the diagnosis was established by x-ray examination (Rieder). Mention should also be made of three cases reported by O. Keller, Spiegel, and Ahrens respectively in which the stomach was found in a femoral hernia. Dreesen records a case of a hairdresser, aged 62, who had an inguinal hernia for nine years with

gastric symptoms for the last three years, such as anorexia, nausea, and vomiting. The presence of the lower part of the hour-glass shaped stomach in the left half of the scrotum was shown by x rays. Bassini's operation was performed under local anaesthesia and complete recovery took place, the form, situation, and function of the stomach being restored to normal. The cause of the gastric hernia in this case is to be found in a gastropothesis which was aggravated by the occupation of the patient, who had to stand in a stooping position for several hours at a time.

### 531. Surgical Treatment of Typhoid Carriers.

W. H. VOSBURG and ANNA E. PERKINS (*Surg., Gyn. and Obstet.*, March, 1925, p. 404) report in detail seven cases of typhoid carriers treated surgically by the removal of the gall bladder and appendix. Subsequent bacteriological examination of the faeces for typhoid bacilli proved almost invariably negative. In all their cases the appendix gave microscopic evidence of previous inflammation, and the authors draw attention to the importance of removing the appendix as well as the gall bladder when operating for the cure of a typhoid carrier. They find that there is a preponderance of women carriers, which they attribute to the greater liability in women to gall-bladder infections; moreover, in their domestic occupations they tend to infect others more frequently than do males. The authors add that there is reason to suppose that in every community there are more carriers than is generally imagined, and that the examination of faeces should be repeated more often than is the present custom.

### 532. Delayed Operation and Appendicitis Mortality.

S. WIDERÖE (*Tidsskrift f. d. Norske Lægef.*, April 1st, 1925, p. 345) publishes the appendicitis statistics from his hospital in Oslo in the period April 1st, 1919, to January 1st, 1925. With only two exceptions his rule was to operate at once on all cases of acute appendicitis in which the signs indicated progress of the disease. Most of the operations were performed under a general anaesthetic, but appendix abscesses were, as a rule, opened under local anaesthesia, the appendix not being removed unless it presented in the incision. Among the 783 cases operated on, there were 20 deaths—a total mortality of 2.55 per cent. The mortality was 5.26 per cent. for the patients operated on within forty-eight hours of the onset of symptoms; it was 3.6 per cent. for the patients operated on within seventy-two hours; and it was 6.8 per cent. for the patients operated on between the fourth and eighth days. The frequency with which the appendix was found perforated at the operation increased uniformly with the length of the interval between the onset of symptoms and the operation; only 6 per cent. of the appendices of the patients operated on within the first twelve hours were perforated, whereas this was the case with 48 per cent. of the patients operated on between the fourth and eighth days. Of the 20 deaths, 10 were due to peritonitis, 3 to embolism of the lungs, 3 to nephritis, 2 to multiple abscesses of the liver, 1 to intestinal obstruction, and 1 to bronchopneumonia.

## Therapeutics.

### 533. Intra-abdominal Infusion of Ether in Peritonitis.

B. GUTNIKOFF (*Zentralbl. f. Chir.*, March 14th, 1925, p. 574), as the result of experiments on dogs, came to the following conclusions: (1) Ether possesses sufficient disinfectant power to destroy streptococci and *B. coli* at the body temperature. Staphylococci, on the other hand, are not destroyed, but are inhibited in their development by the influence of ether. (2) Ether causes a marked hyperaemia of the peritoneum or abdominal cavity, accompanied by a considerable increase in the absorptive power of the abdominal cavity. (3) Prophylactic infusion of ether into the abdominal cavity has a favourable effect. (4) Favourable results are also obtained by infusion of ether in diffuse purulent inflammation due to pure staphylococcal infection. (5) In processes in which destruction of bacteria takes place as the result of ether infusion, and hyperaemia occurs, the results are unfavourable, owing to the liberation of endotoxins and the increased absorptive power of the hyperaemic peritoneum.

### 534. Vaccine Therapy in Measles.

M. B. SINDONI (*La Pediatria*, February 15th, 1925, p. 173) treated with vaccine 18 children from the beginning of the eruptive stage of measles. The vaccine used was prepared by treating cultures of the serum of convalescent patients according to the method of Sison. Sindoni reports that the vaccine shortened the duration of the disease and lessened the severity of its symptoms. Cure followed with no complications, except in two patients in whom broncho-

pneumonia had already developed when treatment started, and in which the disease pursued a benign course, in contrast to the usual course in such cases. Sindoni adds that when estimating the effect of this specific treatment the following facts must be considered. In measles the majority of cases show a typical development, and yet in these vaccinated cases all were abortive, although from the first examination on the second, third, or fourth day of disease the usual course was to be expected. It is notorious that the mortality and percentage of complications in measles in hospital out-patients is very high; in Sindoni's investigation comparative observations were made at the same time of other patients in the same epidemic who received the usual expectant treatment. There resulted a mortality of 18 per cent. and complications in 20 per cent. Although the small number of observations prohibits drawing general conclusions, the impression remained that early vaccination is undoubtedly beneficial and entirely harmless.

### 535. Value of Chloroform in the Treatment of Tetanus.

H. DUFOUR and DUHAMEL, at the meeting of the Société Médicale des Hôpitaux on March 20th, 1925 (*Presse Méd.*, March 25th, 1925, p. 391), reported the case of a patient, aged 23, who had recovered from a severe attack of tetanus following a small suppurating wound of the foot. The patient received 520 c.cm. of tetanus antitoxin in ten days. On the fourth day of the disease he became suddenly worse, and death appeared to be imminent. It was decided to give a subdural lumbar injection of antitoxin under chloroform anaesthesia on account of the marked opisthotonos; 40 c.cm. of serum was injected, and next day the patient appeared to be almost cured. The authors suggest that the anaesthesia aided the action of the antitoxin on the central nervous system. It was generally admitted that symptoms of tetanus might occur after an intensive course of antitoxin, apparently owing to a spastic reaction produced by the injections. In such cases chloroform will check these spasms and produce a rapid improvement. Lesné suggests that the sudden amelioration in this patient's condition may have been due to the known action of anaesthetics in anaphylaxis.

## Laryngology and Otology.

### 536. Infantile Stenoses of the Oesophagus.

A. SARGON (*Arch. Internat. de Laryngol., d'Otol. et de Rhinol.*, April, 1925, p. 412) points out that there are two forms of congenital infantile stenosis of the oesophagus compatible with life: (1) Infantile membranous stenosis, (2) mega-oesophagus which is essentially infantile. Both are exceedingly rare. He gives the detailed history of three cases, two suffering from the first condition and one from the last, and quotes the histories of a large number of cases which have been collected by Dechaume. In cases of congenital membranous stenosis the symptoms are the same as those caused by ingestion of caustics, but in those cases there is only one stenosis. Of the two cases quoted by the author, one occurred in the cardiac region and the other was subphrenic. Dilatations of the oesophagus in infants give rise to the same symptoms as in adults—namely, easy and abundant regurgitation frequently containing retained food—while a radiographic examination shows a large thoracic pocket in the form of a catfish with a flattening at the level of the diaphragm and a recurring through the diaphragmatic hiatus. Catheterization reveals the lengthening of the oesophagus which causes frequent mistakes. Sometimes the operator thinks that he has entered the stomach when he has not passed the cardio-diaphragmatic region. With the oesophagoscope it is possible to penetrate into a large thoracic pocket having sides which are sometimes white and sometimes highly inflamed. It contains more or less decomposed food, which it is very difficult to remove, and which renders the complete examination of the cardio-diaphragmatic region only rarely possible. Congenital infantile stenosis frequently occurs in infants of less than a year old, while mega-oesophagus usually appears later. Regurgitations in cases of membranous stenosis are immediate, small in quantity, and consist of food which has just been taken. In cases of dilatation of the oesophagus regurgitation is abundant and often fetid; it contains food eaten two or three days before. Catheterization gives quite different results in the two forms. Only fine probes can be passed in cases of congenital membranous stenosis, but in cases of mega-oesophagus large bougies can easily be passed, unless the cardio-diaphragmatic region is in a state of spasm. The treatment of infantile membranous stenosis consists in dilatation of the single stenosis, with or without oesophagoscopy, with small bougies which are for preference retained temporarily; very exceptionally internal oesophagotomy may be performed to permit of dilatation. Gastrostomy should

rarely be practised, but, if it is unavoidable, it will be followed by retrograde dilatations in serious cases. The treatment of infantile mega-oesophagus consists, as in adult cases, in general hygienic precautions—careful diet, washing of the pocket, surgical treatment, dilatations with very large bougies, and, when possible, with an air bongo.

### 537. *Dysphonia in Professional Singers.*

C. BIAGGI (*Arch. Internat. de Laryngol., d'Otol. et de Rhinol.*, January, 1925, p. 5), laryngologist to the Scala Theatre in Milan, has had considerable experience of disturbances in the voice production apparatus amongst the great number of singers who pass through that institution. He divides these troubles into three classes. The first includes the chronic dysphonias which follow acute affections of the larynx. The cords are congested, and the movements are inhibited and lacking in tension owing to formation of fibrous tissue between the mucosa and the musculoepitaxial layer. The second group includes the dysphonias due to overuse of the voice. This group was not found among the really great singers, but among those who are training or who are not quite equal to the parts they are attempting. In these cases the cords are rough, tend to be shiny, and have lost their healthy appearance. They very commonly show the typical nodule on the free edge, or there may be a definite polypus. The author has found that in a large number of these cases the trouble is due to the singer attempting to sing a part the range of which is really outside his register. An example is given of a young soprano who had completed her training successfully and had no trouble with her voice until she began to rehearse *Aida*, when her voice became rough and on her vocal cords appeared small nodules which Biaggi removed. She ceased to sing this part and her voice speedily recovered completely. The author gives several examples of how certain works and the writings of certain composers affect the voice in this way. He has found that the music of the older composers is much less likely to harm the larynx than that of the more modern, and always advises a choice of composers accordingly. A third class of dysphonia is due to incorrect methods of voice production. Biaggi describes three methods of producing the voice. (1) In the "coup de glotte" the glottis is kept closed until the pressure in the chest has been raised considerably, producing an explosive type of note. (2) In the "coup de poitrine" the cords are held closely approximated during the first part of expiration; this manoeuvre gives an indistinct sound with a distinct sibilant. These two methods may be used with great success in certain parts by singers who understand their limitations, but when overdone by the tyro have a very bad effect on the sound and on the larynx. The third method is the safest and the most satisfactory, the cords being completely approximated at the very beginning of expiration. This produces the most pleasing tone and the fewest cases of dysphonia. Another type of dysphonia is due to the failure to close the nasopharynx by the soft palate; in the absence of anatomical changes this can usually be corrected by massage of the soft palate. Biaggi's line of treatment is to remove nodules and polypi, to apply a little local treatment such as sprays or gargles, and to correct the faults in the choice of work and in the method of voice production.

### 538. *Ipiodol in Ear, Nose, and Throat Cases.*

L. REVERCHON and G. WORMS (*Rev. de Laryngol., d'Otol. et de Rhinol.*, March 31st, 1925, p. 139) report that they have used Ipiodol with great success in exploration of the cavities of the face and neck. In cases of otitis media they were able to obtain very good pictures of the Eustachian tube after injection of Ipiodol through the pharyngeal orifice. The injection was followed by no untoward symptoms, but with the instruments at present available the process of injection is difficult. It necessitates considerable pressure, a special syringe must be used, the Ipiodol should be rendered more liquid by heating, and complete anaesthesia of the pharynx is necessary. Although it is usually possible in sinusitis to obtain a complete picture by x-ray examination, Ipiodol is said to show more clearly the degree and nature of the lesions and to be particularly applicable in cases of maxillary sinusitis. In these cases 4 to 5 c.c.m. of Ipiodol should be injected into the cavity. The authors believe that no other method gives such an exact picture of the anatomical connections of dental cysts, and that in oesophageal examinations Ipiodol is preferable to barium or bismuth meals, in view of the possibility of tracheo-bronchial connexions in ulcerating carcinomata. The penetration of milk containing bismuth into the bronchi may have grave consequences which do not occur if Ipiodol is used, and it is possible to follow the course of the oil from the oesophagus into the bronchi. The authors report that Ipiodol is particularly useful where it is desired to obtain a true picture of the degree of displacement of the trachea due to goitre or other tumour of the neck. They think that this method will be exceedingly valuable in

exploring the trachea for foreign bodies and tumours, being more convenient than tracheo-bronchoscopy and giving a more accurate idea of size and position. For tracheal injections of Ipiodol the authors recommend ordinary straight needles adapted to a glass syringe; they have never used any special apparatus. They always use the intertracheal path, which is more direct than the subglottic. Anaesthesia is obtained by the injection of 2 to 3 c.c.m. of 1 per cent. cocaine solution, afterwards injecting the Ipiodol very slowly, about 2 to 3 c.c.m. a minute. If a picture of the lung is required it is necessary to put the patient on his side so that the Ipiodol will flow into the desired lung; 7 to 8 c.c.m. of oil is necessary to inject the bronchial system and the inferior lobes of the lung. The authors used this method with success in two cases of dilatation and one of pulmonary abscess without undesirable results. The anaesthetic causes a slight cough, but if it is complete, which is the case after the lapse of fifteen minutes, the injection of Ipiodol is not followed by any reactions.

## Obstetrics and Gynaecology.

### 539. *Haemorrhoids in Pregnancy.*

C. ROSSER (*Amer. Journ. Surg.*, March, 1925, p. 63) points out that pregnancy tends either to initiate or to aggravate haemorrhoids, a combination of factors acting as the predisposing cause. Pelvic congestion and the pressure of the uterus interfering mechanically with the anal and rectal circulation may produce varicosity or increase any already existing varices and cause external piles. In labour itself the dilatation of the sphincters and the local congestion may result in such complications as fissure, haemorrhage, protrusion of the mucous membrane, granulations, thrombosis, or even gangrene. Palliative and prophylactic measures include the prevention of constipation by diet and exercise, and the production of a soft stool by agar and liquid paraffin rather than by salines and castor. Actnal protrusion may be promptly reduced in the knee-chest position. Rosser considers that a haemorrhoidectomy under local anaesthesia is indicated when haemorrhoids appear early in pregnancy, are aggravated by its continuance, or give rise to excessive haemorrhage and ulceration. When thrombosed external piles are present relief may be obtained by removal of the clot and redundant skin. This operative treatment enables the bowel to function in forty-eight hours, and does not interfere with the continuance of the pregnancy.

### 540. *Diphtherial Vaginitis.*

A. F. LASH (*Surg., Gyn. and Obstet.*, April, 1925, p. 556) reports two cases of diphtherial vaginitis. The first patient, aged 44, was acutely ill and presented a foul sero-sanguineous vaginal discharge, with diphtherial membrane lining the vagina. The second patient, a primipara aged 33, developed fever two days after a normal delivery; diphtherial membrane with foul purulent vaginal discharge appeared on the labia two days later. Both patients recovered under antitoxin treatment. Lash remarks that this condition is rare and is more common in children than adults, though its occurrence in a patient aged 55 has been reported. Diphtherial infection of the vagina occurs more often secondary to throat infection than as a primary infection. The mortality is high since the condition is generally recognized late owing to infrequent vaginal examination, but when diagnosed large doses of antitoxin should be given and precautions taken to prevent secondary infection of other mucous membranes. In each of the cases the diagnosis was confirmed by bacteriological examination.

### 541. *Uterine Hypoplasia and Sterility.*

C. A. CASTAÑO (*Gynecol. et Obstet.*, 1925, xl, 3, p. 207) points out that at birth the length of the uterus is 3 cm., of which 2 cm. corresponds to cervix; arrest of uterine development at this stage leads to amenorrhoea and absolute sterility. From the age of 6 the body grows more than the cervix, so that at 10 the two parts are of equal size; arrest of development at this stage leads to uterine hypoplasia, with relative sterility. In such an infantile uterus, which may be strikingly ante-flexed, the cervix is conical and the sound passes from 4 to 5 cm.; some degree of cervical stenosis is present, but its importance, the author thinks, should not be exaggerated. A cervix which will permit passage of the menstrual discharge or of the uterine sound will allow ingress of spermatic fluid; operations for dilatation are therefore unnecessary. According to Recasens, uterine hypoplasia is concerned in 50 per cent. of cases of sterility in urban inhabitants. Endocrine dysfunction plays an etiological part, but for Castaño the ultimate causative factor is almost always a late manifested congenital syphilis. Therapeutically Spanish and other

547. **Transmission of Herpes to Monkeys.** C. R. Soc. de P. TEISSIER, P. GASTINEL, and J. REILLY (C. R. Soc. de Biologie, April 10th, 1925, p. 1015) report that inoculation of the herpes virus into *Macacus rhesus*, *cynomolgus*, and *sinicus* produced no effect, but with *callithrix* positive results were obtained, the skin inoculation with a virus of human origin into this genus of monkey giving rise to eruptions in four out of the five animals tested. In one case the lesions were vesicular pustules, forming an almost confluent mass, but in the other three they were of papular nature, having crusts on the surface; they appeared on the second day after inoculation. There was no general disturbance noticeable, and never any paralysis, which is so frequent in experiments on infected rabbits. Inoculation on to the cornea failed to cause keratitis. Inoculation into the brain with fluid coming from the vesicles of a human case of herpes was likewise without effect, though the same fluid when injected intracerebrally into a rabbit produced fatal encephalitis. Successive inoculations into the skin of the same animal showed that monkeys rapidly acquire an immunity to the virus; after the second inoculation there were only a few discrete eruptions, and after the third and subsequent injections no reaction occurred. The virus was not altered in its passage through monkeys and gave rise to herpes both in man and in rabbits when taken from the lesions in the monkeys.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 558. Persistent Pulse Irregularity and Iodine Hyperthyroidism.

DURING the last five years the iodine treatment of goitre has been extensively used, especially in Switzerland, and O. ROTH (*Wien. Arch. f. inn. Med.*, March 30th, 1925, p. 475) describes eleven cases which he has encountered, in which persistent irregularity of the pulse (arrhythmia perpetua), through auricular fibrillation, was associated with iodine hyperthyroidism. In these cases of long-standing goitre iodine treatment had been employed, and as a result typical symptoms of iodine hyperthyroidism had appeared, with subsequent symptoms of severe cardiac insufficiency. Examination revealed dilatation of the heart, especially of the right side, with a rapid pulse showing the typical persistent irregularity. In seven of these cases the author had examined the heart previously and found no cardiac affection; in two other cases, though a cardiac affection had been detected previously, there had been no persistent pulse irregularity. The connexion of the persistent pulse irregularity with the iodine treatment was shown by the fact that in one case the persistent pulse irregularity was completely and permanently cured by operative treatment, and in two cases by medical treatment. The cases recorded give additional confirmation to the view that persistent pulse irregularity in Graves's disease is a symptom of that affection. They also show that auricular fibrillation in goitre cases, with the so-called idiopathic dilatation of the heart and persistent pulse irregularity, is to be regarded as a condition of thyrotoxic nature. They further demonstrate the danger of iodine treatment.

### 549. Hypertrophic Secondary Syphilide of the Eyelid.

A. LOUSTE and L. LOUET (*Bull. Soc. Française de Derm. et de Syph.*, January, 1925, p. 12) report the case of a woman, aged 36, in whose left inferior palpebral angle there was a painless greyish-pink rounded infiltration, the size of a lentil, projecting from the palpebral margin. It resembled a chancre, and was originally considered to be the primary lesion. Although there was no adenopathy, this hard hypertrophic mucous lesion followed typical cutaneous syphilides. It was found that the patient had had genital and buccal lesions for several months. The primary sore appeared to have been situated in the left tonsil, as the patient had had an "angina" which lasted for three months, accompanied by severe nocturnal headache. She was very anæmic, her skin was covered with hypertrophic syphilides, and the conjunctival lesion was of the same type. The Hecht and Wassermann reactions were positive. Millau had seen similar lesions somewhat frequently when examining the conjunctiva for mucous plaques, but they were seldom so voluminous as in this case.

### 550. Typhoid Peritonitis without Intestinal Perforation.

H. M. GREENWALD and H. ELLISBERG (*Amer. Journ. Dis. Child.*, March, 1925, p. 365), who report a case in an infant, aged 16 months, state that only some fifty cases of peritonitis in typhoid fever without intestinal perforation are on record. With the exception of one in a child, aged 12, reported by Wilson in 1886, the previous cases were all in adults, and the authors' case is the first to be recorded in an infant. Three different opinions are held as to the cause of the condition—namely: (1) that it occurs by direct extension from the lesions in the intestine; (2) that there is a migration of the organisms from some focus in the abdominal cavity, most frequently the small intestine, appendix, and mesenteric glands; and (3) that infarcts in the spleen occur, thus paving the way for the migration of the organisms. The fact that the authors' patient improved rapidly after laparotomy and made an uneventful recovery suggests that neither splenic infarcts nor broken down mesenteric glands were the predisposing factor. As no typhoid bacilli were found in the exudate, the peritonitis probably resulted from direct extension from the inflammatory lesions in the intestinal tract.

### 551. Prophylaxis of Varicella.

Z. VON BARABÁS (*Jahrb. f. Kinderheilk.*, January, 1925, p. 343) employed the following methods of preventing varicella at the Municipal Children's Home at Budapest. (1) Fifty children were inoculated with the contents of fresh vesicles in the skin of the upper arm or subclavicular region. The usual result was local redness and scab formation, lasting one or two days; in only two cases did a few clear vesicles

develop on the scarified skin of the chest on the eighth or ninth day after inoculation, disappearing in three or four days. The author's experience confirms the view that the infectivity of the varicella vesicles is only slight through the skin, and that transmission of the disease probably takes place by droplet infection from the throat. (2) Four cases exposed to infection were injected with serum obtained from a blister produced by blistering plaster, and one developed varicella within twenty-two days. (3) Seven cases were treated by injection of convalescents' serum, and all escaped infection. (4) Forty-two cases were injected with 10 to 15 c.cm. of whole blood from varicella convalescents, and five, or 11.9 per cent., developed varicella—two within ten days, one on the thirteenth, one on the fourteenth, and one on the fifteenth day after the injection of blood. Barabás regards this as the simplest method of prophylaxis, though it is not invariably successful.

### 552. Blood Pressure and Asthma.

W. KERPPOLA (*Acta Med. Scand.*, April 1st, 1925, p. 162) has found that among 200 cases of essential hypertension there were 10 in which characteristic signs of bronchial asthma were present. Most of the asthmatics whose blood pressure he measured were found to have a normal or subnormal blood pressure in the intervals between the attacks. In 20 cases he measured the blood pressure during the attacks of asthma, and in 5 of these he found no appreciable rise of the blood pressure. In the remaining 15 cases there was an appreciable rise of the blood pressure during an attack of asthma, the blood pressure in 12 of those 15 cases having been normal or subnormal before the attack. In these 12 cases the rise of blood pressure ranged from 25 to 100 mm. of mercury; in the remaining 3 cases, in which the blood pressure was abnormally high before an attack, the rise during an attack ranged from only 15 to 25 mm. of mercury. As a rule, the more severe the attack of asthma the greater was the rise of the blood pressure. In 10 cases in which an attack of asthma was stopped by an injection of adrenalin, with or without pituitrin, it was found that the blood pressure began to fall during the first minutes following the injection, the fall being very rapid during the subsequent ten to fifteen minutes. The author suggests that the relief obtained in asthma with adrenalin is due to its paralyzing effect on vaso-constriction, this effect being achieved only when a comparatively large dose of adrenalin, such as 0.5 mg. by intramuscular injection, or 0.1 mg. by intravenous injection, is given.

## Surgery.

### 553. Acute Intussusception in Children.

COMMENTING on 31 cases of acute intussusception admitted to the Children's Hospital in Philadelphia from 1915 to 1924 HENRY P. BROWN, jun. (*Annals of Surgery*, 1925, p. 1064) observes that the mortality toll of this condition is still high. Studying the literature he finds that, with the exception of the good record of Hepsley, surgeons report a mortality of 25 to 60 per cent. In the Philadelphia series there was a general mortality of 20 cases out of 31 (64 per cent.). Of 9 patients on whom operations were performed within twenty-four hours of the apparent onset of the condition—the most favourable time for surgery—3 died; in the forty-eight-hour period 6 out of 9 died. As regards the cause of death in those patients treated early, in whom reduction was easily accomplished, Brown considers that the theory of absorption of toxins from the intestinal tract is the most plausible. He lays stress on the importance of early diagnosis and operation before the stage where reduction is impossible, as the vast majority of cases of resection of intussusception end fatally. The procedure employed in one case is described in detail as worthy of trial in selected irreducible cases when the gut is not obviously gangrenous nor the mesentery thrombosed, only the oedema of the bowel preventing reduction. One blade of a pair of Mayo scissors was inserted in the a-mesenteric border of the bowel, between the intussusciptum and intussuscipium, and the constricted neck of the intussusception cut. After this simple procedure reduction was accomplished with the greatest ease, the 2½ cm. incision in the caecum being easily closed with catgut and a continuous Lambert suture of linen. Brown adds that should reduction still be impossible, and the bowel be found to be, not viable, resection could then be readily performed.

554.

**Thyroglossal Cysts.**

A. P. BERTWISTLE and J. E. FRAZER (*Brit. Journ. Surg.*, January, 1925, p. 561), in a combined paper, discuss the growth and development of the thyroglossal tract, with especial reference to the cysts and fistulae which may develop in it. Frazer, after describing the development of this tract in the embryo, concludes that thyroglossal remnants above the thyroid are few, and, if present, occur usually in the foramen or near the hyoid. Below the hyoid the tract is present completely in many cases and incompletely in others; whether complete or incomplete, the line of the tract extends from the hyoid, usually folded up behind it from below, to the thyroid gland. Any remnants of it may take on further development, especially, perhaps, if a condition of relative hypothyroidism exists. It is possible also that some cells of the tract may separate and lodge below the level of the thyroid; if so, these cells may also be liable to develop further. Cysts lying superficially below and behind the foramen caecum may have a possible origin from the space included between the two halves of the developing hind part of the tongue, and not necessarily be connected with the thyroglossal tract. Bertwistle records details of eleven cases of thyroglossal cysts and fistulae. Their diagnosis is usually easy, but the cysts may be tuberculous, myxoid, or myxoid, which is only rarely the seat of pathological processes. The most common cause of failure in surgical treatment is incomplete removal, but Bertwistle points out that resection of part of the hyoid bone need not be a routine procedure, and that division of the hyoid is rarely necessary if the dissection is continued well behind the bone. He recommends a horizontal incision in the line of the natural crease of the skin of the neck, and believes that no case of carcinoma arising in the tract has yet been reported. He suggests that the thyroglossal fistula is in direct anatomical relation with the thyroid gland, and he agrees that thyroid and parathyroid activities are increased in digestion. He thinks that possibly both the sinus and the thyroid become active concurrently with the salivary glands, having the same nerve supply.

555.

**Pseudarthrosis of the Tibia in Children.**

M. S. HENDERSON (*Journ. Bone and Joint Surg.*, April, 1925, p. 340) describes nineteen cases of pseudarthrosis of the tibia developing in children; in five the fracture was discovered at birth or a few days after; in eight it occurred between the ages of 3 months and 5 years; and in six from 6 to 14 years. The condition, in which there appears to be no attempt at repair, is particularly difficult to treat at any period of life, but in infancy and early childhood it is extremely intractable. Treatment with osteo-periosteal grafts holds out most chance of success, and the later in childhood the fracture occurs the better is the prognosis after operation. Henderson thinks that with fixation and support for one or two years in a walking caliper union might have been maintained in two of his cases in which it had been obtained by operation. He adds, is not justifiable, because the bone becomes more amenable to surgery, and the approach more nearly the percentage of good results that are found in the adult with ordinary pseudarthrosis.

556.

**Polyposis of the Colon.**

J. F. ERDMANN and J. H. MORRIS (*Surg., Gyn. and Obstet.*, April, 1925, p. 460) discuss polyposis of the colon, adenomatous hyperplasia of the intestinal mucous membrane, as distinguished from such polypoid tumours as fibromata, myomata, and lipomata. The condition seems to be a uniform, non-specific reaction to a chronic irritant of a preternaturally varying in size from a split pea to a grape fruit, and having a specific predilection for the lower part of the colon. There are two clinical types: (a) The adolescent type has a tendency to be familial, and in it large numbers of tumours are usually situated in the sigmoid region, and are associated with chronic diarrhoea. (b) The acquired type first appears in adult life; in it the tumours are limited in number, with associated chronic traumatic and inflammatory lesions. Both types show marked predilection for the large bowel and a malignancy incidence of over 40 per cent., with a tendency to chronic unexplained rectal bleeding and diarrhoea, especially when occurring in early life, should arouse suspicion of polyposis of the colon. While the severe haemorrhage, diarrhoea, and high malignancy incidence indicate the need of radical treatment, the inability to predict the extent of the disease renders this difficult, though a radiological examination may be of service. Palliative treatment consists in caecostomy, appendicostomy, irrigations, and radium therapy.

**Therapeutics.****557. Cicatrization of Facial Epithelioma by Formol.**

O. LAURENT (*Le Scalpel*, April 4th, 1925, p. 327) first used formol injections for the treatment of facial epithelioma in 1908, and reports that three of his patients, treated about fourteen years ago, are still alive. In one case the epithelioma had invaded the greater part of the left side of the nose and had extended to the lower eyelid; cicatrization was complete in about three months. In another case a third of the lower eyelid had been destroyed. Cicatrization occurred slowly but completely, after failure of radiotherapy. In two cases seen recently no change was observed after four radiotherapeutic treatments, but in each cicatrization occurred in eight weeks after the commencement of formol injections. Estradéro obtained complete cicatrization in a long series of cases of facial epithelioma. A radiologist who suffered from x-ray dermatitis of the hands with fissures and scabs was much relieved by formol injections, which, however, should not be used in advanced cases with metastases in the cervical lymph nodes; these, Laurent states, require excision and radiotherapy. Under local anaesthesia formol is injected and scattered in droplets at the base of the epithelioma; sometimes it is applied directly to the surface. In early cases one treatment may suffice. Experience enables the operator to limit necrobiosis to the minimum—namely, to a scab covering the ulcer; sometimes cicatrization occurs more rapidly than with x rays. Laurent adds that the success of formol is due to its action (a) as a bactericide, (b) in fixing and hardening protoplasm and especially mitotic nuclei, (c) in restoring deficiency of connective tissue resulting from the malignant growth. He believes that it stimulates the production of connective tissue and also probably of epithelium; it is known to promote new bone formation, and it promotes phagocytosis. He has not observed any well marked difference in its action on the various types of epithelioma and rodent ulcer. He suggests that extensive applications of formol might, in combination with irradiation, enable plastic operations to be performed at an earlier date.

558.

**Calcium Chloride in Nephritis.**

GOUNEAUD (*Journ. de Méd. et de Chir. Prat.*, February 10th, 1925, p. 110) advocates the use of calcium chloride in nephritis even of a subacute character. Two conditions, however, are necessary for success. First, the calcium chloride must be associated with a diet poor in chlorides. Secondly, very large doses, such as 15 to 20 grams per diem, must be given of the anhydrous calcium chloride, which is considerably more than the 50 cg. to 2 grams of the crystallized calcium chloride usually prescribed in nephritis. These high doses in most cases produce an increase of diuresis, a considerable diminution of albumin, an increase in the amount of chloride eliminated, and the rapid disappearance of oedema. They are well tolerated when the renal lesions are not too severe and the circulatory and respiratory systems are acting normally, as is usually the case in recent nephritis and even in the subacute stage. Calcium chloride may be given subcutaneously, by the mouth or by the rectum. Subcutaneously it may be given in a strong solution, as in Lauder Branton's formula of 15 to 20 drops a day of a 1 in 5 solution, or in a weak solution. Calcium chloride is incompatible with the sulphate, boric acid, oxalic acid, sulphuric acid, alkalis, and alkaline carbonates. Its use should not be continued too long, especially in old people and those predisposed to calcium retention, such as subjects of Bright's disease, alcoholism, lead poisoning, and heart failure. In such cases the heart becomes hypertrophied as the result of increase of the arterial tension due to the action of calcium chloride.

559.

**Dosage of Luminal in Epilepsy.**

OSTMANN (*Deut. med. Woch.*, April 10th, 1925, p. 605) has treated 30 cases of epilepsy with luminal, and has arrived at the following conclusions with regard to its dosage in an institution. After the diagnosis of epilepsy has been confirmed by the observation of an attack, 0.15 gram should be given daily in three doses, each of 0.05 gram. If this dosage does not arrest the attacks it should be increased by 0.05 gram until an effect is obtained. When this happens, the same dosage should be continued for four weeks, after which it should be gradually reduced by 0.05 gram at a time until the threshold is found below which the dosage cannot be further reduced without precipitating an attack. Epileptics who have already been for several years in an institution should first discontinue all other drugs and, after the effects of this deprivation have been noted, two doses of luminal, each of 0.05 gram, should be given daily. This dosage is gradually increased, and it may be that the fits will not cease till 0.1 gram is given three times a day. In such cases this dosage should be continued for ten days, and then be

gradually reduced by 0.01 to 0.05 gram. When the minimum effective dose has been found it may be continued for months without ill effects, and it is not necessary to increase the amount. In no case has the author found it necessary to give more than 0.6 gram a day, and when he has not achieved the desired effect with this dose he has often done so by combining the luminal with bromide. Of his 30 patients, 23 responded satisfactorily to luminal alone and the other 2 to luminal supplemented by bromide. In 12 of his cases a certain degree of fitness for work was achieved while the patients were under the action of luminal.

#### 560. Serum Treatment in Scarlet Fever.

K. E. BIRKHAUG (*Bull. Johns Hopkins Hosp.*, February, 1925, p. 134) records the results obtained in thirty-seven cases of scarlet fever treated with convalescent serum, 15 to 85 c.c.m. being injected intramuscularly. While this serum produced consistently a rapid diminution in toxic manifestations, a slight fall in temperature, and increased strengthening of the pulse, it did not affect the duration of the general exanthem, nor shorten convalescence, nor reduce the incidence of septic complications during convalescence. The results obtained with Dochez's scarlatinal antistreptococcal serum in thirty-one cases were strikingly different. A dose of 40 c.c.m. injected intramuscularly during the first three days of the disease caused a prompt disappearance of the toxæmia, a critical fall in the temperature and pulse rate, prompt fading of the general exanthem, rapid reduction in leucocytosis, and rapid disappearance of the glandular enlargement. This dose was sufficient to bring about a clinical cure in moderately severe cases of scarlet fever. Patients treated during the first three days of the disease did not develop complications during their stay in the hospital. The incidence of complications rose rapidly in those admitted after the fourth day of the disease. Dochez prepares his serum by immunizing a horse with strains of the *Streptococcus hæmolyticus* cultivated from the throats or secretions of patients suffering from scarlet fever.

## Ophthalmology.

#### 561. Refraction Changes in Diabetes Mellitus.

W. S. DUKE-ELDER (*Brit. Journ. Ophthalmol.*, April, 1925, p. 167) observes that it is well known that in some cases of diabetes a change of refraction towards myopia occurs, but that it is less well known that a sudden change to hypermetropia may occur. Duke-Elder, from his own cases and from cases collected from other sources, concludes that the change towards myopia can be correlated with an increase in the blood sugar and that the change towards hypermetropia is associated with a decrease in the blood sugar, particularly when the decrease is effected too suddenly. He thinks it probable, therefore, that with the introduction of insulin the occurrence of sudden refractive changes towards hypermetropia will become more marked. He discusses at length various theoretical explanations of the refractive change in the eye itself; he believes the lens is primarily concerned, and suggests that the phenomenon is due to osmotic processes caused by the occurrence of variations of the molecular concentration of the blood and tissue fluids connected with changes in the sugar content. He adds that there is a tendency for the refractive condition to return to the condition prior to the onset of the diabetes in the event of the disease being successfully controlled.

#### 562.

#### Incipient Cataract.

GORDON F. HAWKNESS (*Amer. Journ. Ophthalmol.*, February, 1925, p. 132) describes his trial of milk injections in cases of incipient cataract. He refers to its medical treatment, and discusses such measures as massage, correction of refractive errors, hot applications, diosin drops, sodium iodide drops, fibrolysin, subconjunctival injections of mercuric cyanide, galvanism, and such general measures as Turkish baths, potassium iodide by the mouth, and serological and endocrine therapy. Of his patients treated by milk injections about 50 per cent. showed apparent improvement in vision, but he discounts this result owing to the short space of time during which the cases were watched. It is well known that the vision of patients suffering from cataract may vary from time to time during the progress of the condition which, in the end, reaches maturity. This can be explained partly upon psychological grounds. The author obtained the opinion of forty of the leading American ophthalmic surgeons; of these, twenty stated that they had seen no benefit that could be directly ascribed to medical treatment, and the other twenty had occasionally noticed improvement following medical treatment.

#### 163.

#### Eye Changes in Pregnancy.

J. M. WHEELER (*Med. Journ. and Record*, March 18th, 1925, p. 355), in discussing the eye changes in pregnancy, points out that the enlargement of the pituitary body which often occurs causes a temporary contraction of the visual fields from compression of the chiasma. Central vision is not impaired and the fields do not become sufficiently contracted to interfere with the patient's comfort, nor are there any unfortunate late results. While optic nerve atrophy associated with retinitis may occur late in pregnancy as the result of a toxæmic retrobulbar neuritis the rare possibility of the hypophyseal enlargement becoming great enough to cause pressure atrophy of the chiasma and optic nerves must be borne in mind. Choroiditis may arise as a manifestation of the toxæmia of pregnancy, and prognosis as regards vision is good unless the condition affects the macula, but its occurrence in both eyes, or in a patient's only good eye, might necessitate the induction of labour. Impairment of vision from spasm of accommodation may arise and persist for a few weeks after delivery, but relaxation usually occurs without serious consequences. Haemorrhagic retinitis is always a serious complication, and a prompt termination of the pregnancy is usually necessary since partial or complete blindness in both eyes generally results if the retinitis is allowed to persist. Wheeler also mentions the rarer condition of nraemic amaurosis, when blindness occurs without any abnormal ophthalmoscopic findings, the condition being due to the nraemia acting on the brain cells and not on the optic nerves. Prognosis is good if the patient recovers from the nraemia.

## Obstetrics and Gynaecology.

#### 564. Morbid Conditions of the Endometrium.

W. LAHM (*Zentralbl. f. Gynäk.*, March 28th, 1925, p. 689), by comparison of the results of microscopic examination of endometrial curettings and the clinical histories of the individual patients, feels justified in describing two fairly typical groups of cases. In the first the microscopical appearances suggest an existing or just interrupted early pregnancy, with notable glandular vascular hypertrophy and "slight decidual change"; ovarian fragments or remnants are, however, absent. The patients concerned, 25 to 45 years old, have begun to menstruate comparatively late and continue to do so until they are relatively fecund. Their type of post-menstrual metrorrhagia, and are usually preceded by a period of amenorrhoea. Dysmenorrhoea is quite exceptional, but in many cases the irregular haemorrhages follow a pregnancy or abortion. A persistent corpus luteum is possibly an important etiological factor. The second group includes sterile women whose menstruation is regular, not excessive, but extremely painful, and in whom the uterus is of small or infantile dimensions. The curettings seem to indicate a temporary displacement of the cyclical changes, so that appearances of the premenstrual phase are observed comparatively early after the last menses; the interstitial tissue is, however, thicker and more vascular than usual for the premenstrual phase. Lahm is inclined, like Temesváry, to regard these as cases in which menstrual desquamation of the endometrium has not occurred; such an explanation would bring the microscopical appearances into correspondence with the clinical report of severe dysmenorrhoea.

#### 565.

#### Utero-axnaxal Tuberculosis.

M. REEB (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, 1925, 3, p. 267) describes the following three cases: (1) A woman, aged 26, five years after the birth of her first baby, suffered from abdominal pain and swelling accompanied by profuse menorrhagia and metrorrhagia. At operation ascites and tuberculous peritonitis were noted, with secondary tuberculosis of the uterus and both Fallopian tubes, which were removed. The patient appeared cured after a year's medical treatment and heliotherapy. (2) The second patient, a nullipara, diagnosed as a case of extrauterine gestation, was operated on ten years after laparotomy for tuberculous peritonitis; recent tubercle formation was seen on the parietal and visceral peritoneum, and secondary tubal infection and early tuberculous infection of the endometrium were noted. Cure followed a radical excision. (3) A sterile patient, aged 53, had hard pelvic and abdominal tumours, an enlarged uterus, and ascites; the preliminary diagnosis made was malignant disease of the ovary, but an operation revealed extensive uterine tuberculosis (the body being filled with caseous debris), cicatrizing tubal tuberculosis, and massive tuberculosis of the right internal iliac glands. Cure followed removal of the diseased parts and heliotherapy. It is noteworthy that fever was absent in all these patients, although

in two acute symptoms were present before the operation; that all bad metrorrhagia and monorrhagia (probably attributable to the uterine disease, for oligomenorrhoea is the rule in adnexal tuberculosis); that in two patients the tuberculous disease of the uterus was not diagnosed before or even during the operation—an argument in favour of radical intervention; and that the ultra-violet rays and exhibition of arsenic were found to be of value.

#### 566. The Abortifacient Action of Lead.

W. BLAIR BELL, B. A. HENDRY, and H. E. ANNETT (*Journ. Obstet. and Gynaecol. of the British Empire*, Spring, 1925, p. 1), from experiments on the pregnant rabbit, conclude that the action of lead as an abortifacient is due to a specific lethal effect on the chorionic epithelium. They find that abortion occurs in all pregnant does which receive intravenously 12.5 c.cm. of 0.1 per cent. lead suspension; the minimum lethal dose to the mother is about twice as great. At the same time there is no evidence of general poisoning and no lesion is found in the wall of the uterus, liver, kidneys, or blood; recovery after abortion is rapid and complete. The earliest pathological change is a coagulation necrosis in the trophoblastic tubules of the foetal placenta; the maternal placenta is affected later and less extensively. The older view that abortion from lead is due to production of placental haemorrhages is stated to be erroneous; the vascular changes following the coagulation necrosis are those of thrombosis. The authors are satisfied that luteo in pregnancy, after the chorionic epithelium has ceased to function, lead may also cause abortion by poisoning the foetus, the death of which leads to emptying of the uterus. The abortion following administration of copper to the doe early in pregnancy is not due to a specific action on the chorion, but to haemorrhage in the uterus; no such specific action is shown by thallium or thorium.

#### 567. The Dangers of the Glass Catheter during Labour.

K. SEYNSCHE (*Deut. med. Woch.*, April 17th, 1925, p. 660) comments on the danger of using the glass catheter during labour. In his own experience catheterization of the bladder in two cases was followed by breaking of the catheter and the retention of part of it in the bladder. In one case a pregnant woman complained of pain in the bladder region which persisted during micturition. The practitioner interpreted this as evidence of catarrh of the bladder, and while using a glass catheter he broke it against the vessel into which the urine was running, part of the catheter remaining in the bladder. A urologist then discovered the head of an infant in the vulva. Labour was completed in hospital, and soon afterwards the bladder was opened and a piece of glass catheter 5 cm. long was removed. Uneventful recovery followed. In the author's hospital in Essen the glass catheter is not used during labour.

## Pathology.

#### 568. Spontaneous Immunization to Diphtheria.

C. ZOELLER (*Rev. d'Hygiène*, February, 1925, p. 103) has introduced a test which reveals the presence or absence of allergy to the diphtheria bacillus. It is performed in the same way as the Schick test, except that the fluid injected intracutaneously is not standardized diphtheria toxin, but a 1 in 100 dilution of Ramon's diphtheria anatoxin. In the case of a positive reaction a diffuse redness develops round the site of inoculation after twenty-four hours, accompanied sometimes by slight infiltration; in a negative reaction there is no change visible. This reaction appears to be due to a sensitization to the antolysed proteins in the anatoxin, and to indicate that the person who gives it has already been in contact with diphtheria. If combined with a Schick-negative reaction, it shows that he is already immune; if a positive anatoxin be combined with a positive Schick reaction, it indicates that he is in the process of becoming immunized. If such a person is infected with the diphtheria bacillus, he will develop a mild form of the disease; and if he is artificially vaccinated, he will become immune more rapidly than a Schick-positive, anatoxin-negative person. By these two tests it is possible to divide a population into four groups: Group 1 is Schick-positive, anatoxin-negative, and is highly susceptible to diphtheria; Group 2 is Schick-positive, anatoxin-positive, and is slightly susceptible to diphtheria; Group 3 is Schick-negative, anatoxin-positive, and is fairly well immunized; Group 4 is Schick-negative, anatoxin-negative, and is thoroughly immunized. Using these two tests the author studied four regiments at Mainz, two of which were badly infected with epidemic diphtheria, and two of which were only mildly affected. Among the first two, Group 1

amounted to 11 and 5 per cent.; among the second two to 22 and 28 per cent. Again, among the first two, Groups 2 and 3 together amounted to 61 and 73 per cent.; among the second two to 57 and 59 per cent. From these figures it appears that those regiments which had been most in contact with diphtheria had become most immune. During the progress of the epidemic there is not only an outbreak of clinical cases of the disease, but a development of latent immunity; while the infection with the Kiebs-Loeffler bacillus causes diphtheria in some persons, it leads to the acquisition of an active immunity in others.

#### 569. Diazo-reaction in Urine.

G. HUNTER (*Biochem. Journ.*, vol. xix, No. 1, p. 25) has attempted to systematize the different types of diazo-reaction in normal and pathological urines. Ehrlich's diazo-reaction consists of two stages—a primary colour reaction in acid solution and, after adding ammonia, a secondary colour reaction, with a red foam on shaking. This secondary reaction in alkaline solution was originally supposed to be diagnostic of typhoid, measles, certain types of tuberculosis, and other disorders. But a positive reaction was found to occur also in a fairly large proportion of normal urines. The primary reaction in acid solution appears to be specific for bilirubin, and this test has recently been used in blood serum to distinguish certain types of jaundice. Hunter has specially concerned himself with the diazo-reaction in alkaline solution, working with the reagent of Koessler and Hanko. To 5 c.cm. of 1.1 per cent. sodium carbonate in a test tube is added 2 c.cm. of the sulphuric acid reagent. The contents are mixed by shaking the tube without inverting it. After about a minute one drop of urine is added. One of two distinct phenomena may occur: (1) In all urines a faint yellow colour is produced, which grows more intense for three or four minutes, not generally exceeding a pale orange tint, but it may show a pink tinge and occasionally quite a marked red. The substances in urine mainly responsible are urobilinazoles, phenols, purines, and probably unknown chromogens. It is of little value as a biochemical test. (2) In the urine of typhoid fever and measles patients a bright orange-red colour appears in the solution immediately the drop of urine is added, but the colour disappears in a few seconds. Thereafter there is an intensification of colour, due to the substances responsible for Type A reaction. Hunter believes that this reaction has not been described previously.

#### 570. Intradermal Vaccination against Anthrax.

E. NICOLAS (*C. R. Soc. de Biologie*, March 13th, 1925, p. 593) reports on the effect of intradermal vaccination against anthrax on 8,912 horses and mules. He injected doses of 0.25 c.cm. of Pasteur's vaccine into three separate places on the skin of one side of the neck; six days later injections were similarly given on the opposite side of the neck. The animals were allowed to rest on the day following each injection. No reaction followed the first dose, but in 2.2 per cent. of animals receiving the second dose a swelling appeared at the site of injection, usually within a fortnight, and resolved spontaneously or after the administration of anti-anthrax serum. In a few cases swellings developed at a point remote from the site of injection; two animals so affected died. Small abscesses or superficial sloughing at the injection site were occasionally encountered. Only four cases of anthrax occurred during the following nine months—an incidence of 0.045 per cent. During the previous four years, when no preventive vaccination was employed, but only sero-vaccination in infected areas, the annual death rate was 0.81 per cent., or nearly twenty times as great.

#### 571. Laboratory Findings in Glandular Fever.

R. GILBERT and M. D. COLEMAN (*Amer. Journ. Hyg.*, January, 1925, p. 35) discuss an epidemic of considerably over one hundred cases of glandular fever which occurred during the late winter of 1923 and the early spring of 1924 in the eastern part of Wayne County and adjacent parts of New York State. The first cases were very mild and were believed to be common colds. More serious cases followed, and were regarded as mumps or influenza, the correct diagnosis being finally reached by the district state officer, who made an epidemiological study of the outbreak. *Streptococcus hemolyticus* was isolated from the pus of an axillary abscess and from four of seven throat cultures. Streptococci producing methaemoglobin were present in all but one of the seven throat cultures. Blood examinations were made in 30 cases: 7, or 23.3 per cent., showed polymorphonucleosis; an increase of eosinophils was seen in 66 per cent.; and 22, or 73.3 per cent., showed an increase of lymphocytes. These observations thus agreed with those made by Longcope in the United States, and by Tidy and Daniel in this country.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 572. Fusio-spirillar Pulmonary Gangrene and Military Tuberculosis.

R. DUPÉRIÉ and P. CADENAULE (*Gaz. hebdom. Sci. Méd. de Bordeaux*, March 15th, 1925, p. 163) record a case in a female infant, aged 2 years, admitted to hospital for cough and loss of flesh during the previous six months. On admission dullness, weakness of breath sounds, and subcrepitant râles were found at the right base. Four days after admission the breath became very fetid, and examination of the sputum obtained from the pharynx showed numerous organisms, among which fusiform bacilli and spirilla predominated. Death occurred ten days after admission. The autopsy showed right pyopneumothorax, gangrene of the right lung, and military tuberculosis of the lung and spleen. Fusiform bacilli and spirilla were found in large quantities in the walls of the gangrenous lesions. The lesions found were not those of embolic gangrene, and there was no otitis, appendicitis, or any other affection present liable to give rise to metastatic gangrene. The fusio-spirillar infection probably originated in the bucco-pharyngeal region, and, favoured by pre-existing tuberculosis, spread to the smallest ramifications of the bronchi. The pulmonary lesions were of the bronchopneumonic type, with foci disseminated throughout the lobules.

### 573. Prognosis of Chronic Infective Endocarditis.

ACCORDING to reports in medical literature, chronic infective endocarditis is nearly always fatal; but A. D. BIGGS (*Arch. Intern. Med.*, March 15th, 1925, p. 402) records that of 57 patients with bacterial endocarditis treated at St. Luke's Hospital, Chicago, 24 are living, and many of them seem to have recovered from the heart-valve infection. Biggs states that in order to make the diagnosis certain the clinical indications of the disease need to be supported by demonstrating the presence of bacteria in the blood. Pathogenic bacteria were detected by blood cultures in each of the cases of the disease at St. Luke's Hospital: in 54 of the 57 cases the organism was the *Streptococcus viridans*; in 3 cases haemolytic streptococci were found. Almost all of the 24 patients living are without fever or other signs of infection, and many are able to do light work. One has been well for thirteen years, two for seven years, one for two and a half years; thirteen are in the second year and seven in the first year of clinical observation.

### 574. Erythromelalgia as a Complication of Rubella.

A. GANS (*Nederl. Tijdschr. v. Geneesk.*, April 25th, 1925, p. 1915), who records an illustrative case, states that erythromelalgia is usually an entirely independent condition, though occasionally it may be a manifestation of nervous or vascular disease. Cassirer distinguishes two forms of erythromelalgia. The first occurs in the areas served by definite nerves, and is explained as an irritative condition of the peripheral nerves, especially of the vaso-dilator and secretory fibres. The second form, in which the extremities of the limbs are attacked, is closely related to aeroparaesthesia and Raynaud's disease, in which last condition the vaso-constrictors, and not the vaso-dilators, are affected. Gans's case occurred in his own daughter, aged 8, who during the last days of the incubation period of rubella developed attacks of erythromelalgia in both feet, lasting for about an hour. A few days after disappearance of the rash the attacks ceased. Gans suggests that the swollen lymphatic glands were the cause of the attacks, owing to their pressure on the sympathetic ganglion or peripheral vaso-dilator fibres. This supposition is supported by the fact that the glandular enlargement appeared some days before the eruption, and was still perceptible a day before the last attack of erythromelalgia.

### 575. Vesicular Eruption during Antirabic Treatment.

D. IONESCO (*Bull. et Mém. Soc. Méd. Hôp. de Bucarest*, January 14th, 1925, p. 14) remarks that the most important complication of treatment for rabies is the occurrence of transient paralyses. Various eruptions, such as urticaria and erythema multiforme, may also occur. He reports a case in a boy, aged 14, who on the eighth day of treatment for a bite on the lip developed a generalized papulo-vesicular eruption which lasted six days; it was accompanied by an eosinophilia of 4 per cent, and a generalized enlargement of the lymphatic glands. Ionesco has been unable to find any similar cases on record.

### 576. Association of Diabetes with Tuberculosis.

E. LUNDHOLM (*Acta Med. Scand.*, April 1st, 1925, p. 1) gives an account of fourteen cases of combined diabetes and tuberculosis in which a detailed study was made of the action of insulin and the effect of the tuberculosis on the patient's carbohydrate tolerance. It was found that as the tuberculosis advanced the glycosuria and acetouria regressed, carbohydrate tolerance increased, and the patient's insulin requirements decreased. Further, it was noticed that the patients undergoing insulin treatment were subject to attacks of sudden hypoglycaemia. The ultimate cause of death was tuberculosis in every case, not diabetes. The author believes he has discovered in the tissues of the tuberculous patient a substance reducing the blood sugar. He has not been able to demonstrate this substance, which he calls para-insulin, in tubercle bacilli, in tuberculin, or in the tissues of healthy persons. With regard to the treatment of diabetics suffering from tuberculosis, he advises a régime suitable for both diseases; plenty of food, rich in carbohydrates, should be given, and the dosage of insulin regulated according to the amount of food consumed and the patient's general state of health.

### 577. Infantile Eczema and Food Proteins.

F. J. CORPHER (*Amer. Journ. Dis. Child.*, March, 1925, p. 354) reviews a series of 100 cases of true infantile eczema treated, on the evidence of a positive skin reaction to food proteins, by elimination or reduction of the offending element. Of the 53 infants showing positive skin reactions only 38 were found to be proper subjects for this study. It was noted that positive reactions might be obtained to proteins not included in the dietary. Of the 38 cases recorded improvement occurred in 14, and a definite subsidence of symptoms in 7. Patients sensitive to animal proteins were found more likely to respond to specific treatment than those sensitive to cereals, fruit, and miscellaneous proteins. The author thinks that though positive cutaneous reactions are undoubtedly associated with infantile eczema this relationship should at present only be regarded as a guide to diagnosis and treatment, and as a possible stopping-stone to the discovery of the actual etiology.

## Surgery.

### 578. Treatment of Peptic Ulcers.

A. EISELSBERG (*Acta Chir. Scand.*, March 21st, 1925, p. 71) gives an account of the progress made in the operative treatment of gastric and duodenal ulcer in his hospital in Vienna, where there has of late been a considerable increase in the number of such cases. This increase may, he suggests, be partly due to such influences as the coarse food entailed by the war. Since 1918 about 900 operations have been performed at his hospital, the operation mortality being 4.45 per cent. Some of these operations were performed for stenosis of the stomach. The operations most in favour were Billroth's resections—132 Billroth I and 466 Billroth II operations being performed. Transverse resection was performed in only 41 cases, and gastro-enterostomy in 82 cases. The place of gastro-enterostomy, the most popular operation for some decades, has now been largely taken by resections, but the author doubts whether this vogue will last. It is distasteful to him to resect a large part of the stomach and all of the pylorus when he finds a single small ulcer, and he confesses to feeling horrified when he finds, after resecting the pylorus on the strength of a careful consideration of the symptoms, a positive x-ray examination, and apparent hardness of the pylorus, that there is no sign of ulcer in the parts removed. He foresees a time when it may be possible, by operating on the abdominal sympathetic system, to dispense with resections, but in the meantime these operations are the best—for this reason, among others, that they remove malignant growths in the rare cases in which they simulate ulcers.

579. D. C. BALFOUR (*Minnesota Medicine*, April, 1925, p. 218), reviewing the various methods of treatment of gastric and duodenal ulcers, points out that the kind of treatment depends largely on the site of the lesion. In chronic gastric ulcer prolonged medical treatment is justified only when surgery is absolutely contraindicated by the patient's age or condition, though, as a temporary expedient, medical treatment may be valuable in improving the condition of patients who are exhausted by repeated haemorrhages, extensive

subacute local inflammation, or toxæmia from gastric stasis. On the other hand, in duodenal ulcer the symptoms are usually less severe, and both the disability and the danger of fatal complications are less than in gastric ulcer. Certain forms of duodenal ulcer are relieved by medical treatment; *post-mortem* evidence shows that ulcers may heal spontaneously, and one thorough course of medical treatment of uncomplicated duodenal ulcer is generally considered justifiable before surgical intervention is advised. Cases suitable for medical treatment are: (1) Patients under 25 years of age; (2) patients with mild and recent symptoms; (3) patients in whom ulcer is found incidentally, as in skiagrams; and (4) patients whose age or general condition make operation a greater menace than the ulcer. In the majority of cases, however, surgical treatment is sooner or later required. Balfour states that, in chronic accessible gastric ulcer, excision with gastro-enterostomy gives good results, while for large ulcers partial gastrectomy is the operation of choice. All chronic gastric ulcers are potentially malignant. Gastro-enterostomy alone should be reserved for cases in which it is impossible to remove the lesion. He cites the statistics of the Mayo Clinic for the period 1914-24, when 1,228 operations for chronic gastric ulcer were performed, gastro-enterostomy being employed in 250 (20.3 per cent.) only. In duodenal ulcer, he adds, four operations should be considered: (1) gastro-enterostomy, with or without excision of the ulcer; (2) pyloroplasty or gastro-duodenostomy, with or without excision; (3) excision only; and (4) partial gastrectomy. Balfour recently investigated 1,000 cases of chronic duodenal ulcer in which gastro-enterostomy had been performed more than ten years previously, and found satisfactory results in 88 per cent. In the Mayo Clinic out of 6,665 operations for chronic duodenal ulcer gastro-enterostomy was chosen in 86.35 per cent. The advisability of excision of the ulcer must be determined in each case, but, at the Mayo Clinic, excision of the duodenal ulcer in addition to gastro-enterostomy was practised in only 2.18 per cent. of the cases. Balfour adds that at the Mayo Clinic the results of pyloroplasty have not been as satisfactory as those of gastro-enterostomy. While permitting inspection of the pyloric and duodenal mucosa, it is less effective in reducing gastric hypacidity. In the series of 6,665 cases pyloroplasty and gastro-duodenostomy were performed in only 4.07 per cent. A small non-indurated ulcer in the anterior wall of an easily mobilized duodenum is excised without difficulty, but this does not protect the patient from further ulceration. Partial gastrectomy for duodenal ulcer has been advocated recently, but it is unlikely to be adopted generally, though for gastric ulcer it may be amply justified.

#### 580. Treatment of Cancer of the Bladder.

MARTIN (*Journ. d'Urol.*, March, 1925, p. 232) points out that certain writers have described cases of bladder tumour which have been apparently cured by means of deep x-ray therapy. He himself has never come across such a case, but, on the contrary, records a case in which the treatment has tended to accelerate the course of the growth. The patient in his case was 70 years of age and had had severe hæmaturia for three or four months. Cystoscopy showed a small area of malignant growth in the bladder. Surgical intervention for its removal was refused, and several applications of deep x rays were given. For a few months following this treatment there was a distinct improvement in the symptoms; this was followed by a recurrence of the pain and frequency. Cystoscopy showed that the growth was considerably larger in extent. To relieve the patient's sufferings cystotomy was carried out, but the encephalia was progressive and death soon followed. Martin does not publish this case to discourage others from trying treatment by deep x rays, but he considers it wise that both the good and bad results should be recorded. This case seemed very favourable for treatment by deep x-ray therapy, but, so far from being improved, it appeared that the treatment tended to hasten the fatal termination.

#### 581. The Origin of Prostatic Hypertrophy.

F. REISCHAUER (*Zentralbl. f. Chir.*, March 7th, 1925, p. 517) states that, after many differences in opinion as to the nature of enlargement of the prostate, most investigators have accepted the early view held by Virchow—that it is a tumour formation. The views that it was due to inflammation, arterio-sclerotic changes, or an overgrowth caused by disturbance of the endocrine glands, have met with such frequent and well merited opposition that they need no further consideration. Reischauer, who has examined 130 prostates in the Pathological Institute of the Hamburg-Barmbeck General Hospital, has come to the conclusion that prostatic hypertrophy is much more frequent than clinical examination would suggest. It rarely occurs before 50, invariably physiological, or due to chronic inflammation. After 50 prostatic hypertrophy is very frequent. Typical

formation of nodules in the usual site is found in over 40 per cent. between the ages of 50 and 60, in 75 per cent. between 60 and 70, and at a later age it is almost constant. Senile atrophy therefore cannot be the predisposing cause, as maintained by Simmonds. The autonomous growth of the nodules, the extraordinary size of some of the tumours, by which the weight of the organ is sometimes increased tenfold, their parasitic situation, the readiness with which they can be enucleated, and the frequency of recurrence after extirpation, are all in favour of a tumour formation. Reischauer concludes that the cause of prostatic hypertrophy will only be determined when more is known about the cause of tumour formation in general. The conception, however, of prostatic hypertrophy as a tumour formation does not exclude the etiological importance of the sexual glands.

## Therapeutics.

#### 582. Alpha-Jobelin in Collapse.

KURT PETERS (*Med. Journ. and Record*, March 18th, 1925, p. 346) advocates the specific method of treating collapse by stimulating the respiratory centre with the alkaloid alpha-jobelin. He considers that its value in all forms of partial or complete central respiratory depression has been established by exhaustive tests, the respiratory centre being stimulated directly, and so bringing about an increase in volume and vigorous interchange of gases. Becoming effective immediately after injection, it was operative from half an hour to an hour and a half, and it could be repeated frequently or rendered continuously effective by prolonged infusion, without danger of a cumulative effect. In twelve resuscitation experiments intravenous injection of 0.002 gram of alpha-jobelin produced an immediate increase in the frequency and amplitude of respiration, and saved life after respiration had been partly or wholly stopped by a mixture of carbon monoxide with air. Peters considers that it is indicated in all conditions of apnoea or oligopnoea, but not in dyspnoea, where the centre is already reacting to carbon dioxide stimulus. In collapse, shock, paralysis of the centre by poisoning with ether, chloroform, morphine, or carbon monoxide gas, and in acidosis, asphyxia neonatorum, drowning, and surgical shock its rapid action and convenience of administration offer obvious advantages over artificial respiration, oxygen inhalation, and cardiac stimulants.

#### 583. Dosage of Neosalvarsan in Syphilis.

TEODOSIJEVITS (*Dent. med. Woch.*, April 10th, 1925, p. 608) has found that by giving neosalvarsan in a 10 per cent. solution of calcium chloride it is possible to increase the dose of the former considerably. In about 100 cases thus treated he has found that 0.75 to 0.9 gram of neosalvarsan may be given at one injection, the total quantity of neosalvarsan given thus in one course being 4.5 to 7.2 grams. When he gave the injections to patients in the sitting posture collapse occasionally occurred, and in one case it was necessary to administer caffeine and camphor for six hours. Some of the patients suffered from nausea, vomiting, lassitude, and tooth-chattering for several hours; but when the patients were given the injections in the recumbent posture no ill effects followed. The therapeutic effects with this dosage were much better than those with a smaller quantity and no calcium chloride, and the author has not yet seen a definite case of relapse after this treatment.

#### 584. Ultra-violet Rays in Tuberculosis.

E. MAYER and M. DWORSKI (*Ann. Mod. Report Trudeau Sanatorium*, 1924, p. 146) report the results of using the rays of the mercury-vapour lamp in experimental tuberculosis of the cornea of rabbits, and inhalation tuberculosis in primarily infected and sensitized guinea-pigs; they also investigated their bactericidal action. They conclude that the healing of corneal tubercle in rabbits is definitely influenced by ultra-violet light, but that overexposure may irritate rather than heal. Instillation of a 1 per cent. aqueous solution of cosin during irradiation appeared to assist the healing action, but a saturated aqueous solution of quinine was found too irritating. In inhalation tuberculosis irradiation had no definite action upon the disease, and the skin tests were positive alike in control and treated animals. In sensitized guinea-pigs ultra-violet irradiation appeared to modify the course of infection, as shown by the intracutaneous tests, but in those infected subcutaneously autopsy findings showed no material difference between the exposed animals and controls, so that no conclusive deduction could be made. Exposure of tubercle bacilli for varying periods to the rays indicated that the rays were bactericidal, but that longer exposures were required to destroy the bacilli when mixed with quinine; it is suggested that this is due to the power of quinine to absorb ultra-violet rays.

## Dermatology.

## X-ray Dermatitis.

585. W. DURRENLIH and DAVID CHAUSSÉ (*Ann. de Derm. et de Syph.*, March, 1925, p. 161) remark that the usual division of x-ray dermatitis into acute and chronic requires modification. The dermatitis of x-ray workers is chronic in regard to cause and effect, being due to the prolonged accumulation of small doses and characterized by lesions resembling those produced by prolonged exposure to sunlight—pigmentation, hyperkeratosis, epitheliomata, and ulceration, probably of neuritic origin. The so-called acute dermatitis occurring in patients is only acute in respect to the cause; its effects are often very persistent. It is due to a single excessive irradiation, or to relatively strong and frequently repeated irradiations, having a cumulative effect. The symptoms may be clearly acute, the dermatitis supervening about fifteen days after irradiation, persisting for a few weeks or months, and resulting in a characteristic scar—firm, waxy, streaked with white or brown patches, and numerous telangiectases. These scars are always liable to break down, either spontaneously or as the result of an injury; ulceration resembling in every respect the initial lesion may develop after many years. Darier reports such a case occurring twelve years after a series of mild but numerous irradiations given at short intervals; after twelve years the histological lesions closely resembled those of a dermatitis of five or six months. Arnould has reported the case of a woman treated by radiotherapy in 1918 for uterine fibroma; extensive and severe scars resulted. The fibroma in 1919 required operation, and the incision was carried through the scars. The deeper structures healed normally, but the skin edges ulcerated rapidly, presenting all the signs of an acute x-ray ulcer and not healing for ten months. The present authors record similar cases. They describe in detail the sharply cut circular or oval ulcer, noting that its floor is covered by a thick yellowish-white opaque slough, tough and adherent. This is sometimes perforated here and there by bright red projecting granulations which are part of the healing process. Doubt often arises whether the lesion is an x-ray ulcer or a recurrence of an epithelioma which has been irradiated. Differential diagnosis may be difficult, as an epitheliomatous ulcer may exhibit the cream-coloured slough of an x-ray ulcer, and may be surrounded by a zone of atrophic skin, left by previous irradiations; the diagnosis can only be determined by histological examination. If there be an epithelioma thorough irradiation should cure it, but if there are epitheliomatous masses buried in sclerosed scar tissue the difficulty is great. These x-ray ulcers may persist for months or years without change except for the appearance of the bright red projecting granulations, which gradually extend and absorb the slough. At any time the resultant scar may break down, either without obvious cause or following an insignificant injury or a surgical incision; in such a case the ulcer will exhibit all its original characteristics. The authors describe the histological structure of the scar tissue in their cases in detail.

## 586. Leiomyoma Cutis.

O. S. ORMSBY (*Arch. Derm. and Syph.*, April, 1925, p. 466) reports two cases of leiomyoma cutis and gives brief notes of forty-seven others in the literature. Occurring rather more often in males than in females, the disease is characterized by numerous firm, pink or brown, translucent painful nodules, the size of peas, generally appearing on the extensor surfaces of the extremities, and more rarely on the trunk, face, forehead, neck, and nose. They average in number from twenty to a hundred, and in only four cases was a single lesion present. Though varying in density they all contain interlacing masses of smooth muscle fibres, apparently arising from the arrectores pilorum. The lesions, which may often be painless when small, are painful when they become larger, paroxysms of severe pain being readily induced by pressure, irritation, or exposure to cold. Usually the disease progresses slowly, and in only one case did spontaneous disappearance of the lesions occur. The amount of elastin in the nodules and the compactness of the muscle elements vary; the pain appears to be due to pressure on nerve fibres. The cause is unknown. Treatment consists in excision when practicable, removal by electrolysis, or freezing with carbon dioxide snow.

## 587. Eczemas of Bakers and Confectioners.

R. P. WHITE (*Brit. Journ. Derm. and Syph.*, April, 1925, p. 163), from an experimental and clinical study of the eczemas of bread bakers and confectioners, concludes that there is no eruption specific to, or distinctive of, these industries. The eczematous disorders which occur appear to be incidental to, rather than consequences of, the work. Notes are given of four cases out of over a dozen observed;

all the patients had been officially certified, and were receiving compensation for an occupational skin disease. In White's experimental work a nurse and an orderly wore on the upper arms dressings composed of ingredients used in bread-making, and confined their ordinary work. None of the ingredients in a dry state, even if kept in contact with the skin for many days, caused an eruption; but local, non-recurring eruptions occurred when certain wet pastes, moistened night and morning, were used.

## Obstetrics and Gynaecology.

## 588. External Fistulae of the Uterus and Tubes.

L. PUCCIONI (*Rivista d'Obst. e Gynecol. Prat.*, March, 1925, p. 11) records the cases of two women in whom, two years after Caesarean section, a probe passed through an abdominal fistula in the scar area encountered a sound passed into the uterus per vaginam. In the first case there was a purulent, and in the second a faeco-purulent, abdominal discharge; in both cases this contained blood at the time of menstruation. In the first case subtotal hysterectomy was performed; in the second the fundus uteri communicated with the sigmoid flexure as well as with the exterior, and a good result was obtained from conservative treatment consisting in excision of a wedge of fundus and of one ovary, which was cystic. F. FORMICINI (*Ibid.*, p. 7) describes a case of abdominal fistula three years after external incision for right parametritis; an organized tissue protruded externally, and was recognized as the Fallopian tube by the fact that it bled during menstruation and from microscopical examination of an excised piece. The fistula closed after removal of the tube and ovary of the same side, the peritoneal cavity not being reopened.

## 589. The Treatment of Placenta Praevia.

SALLY HJELT (*Finska Läkaresällskapets Handlingar*, March, 1925, p. 238) publishes an analysis of 118 cases of placenta praevia observed in the period 1910-24 in the University Maternity Hospital in Helsingfors. The incidence of this complication of pregnancy in the hospital was 0.32 per cent., and of the 23 cases of total central placenta praevia only 3 were observed in primiparae. The treatment adopted in most cases consisted of version; in 37 cases the membranes were ruptured intentionally, and in 26 cases Braxton Hicks version was performed. Of the 37 cases treated by simple rupture of the membranes only one terminated in the death of the mother, its cause being sepsis. In as many as 28 of these cases the puerperium was perfectly normal and uncomplicated by fever. Eight of the infants died during labour, and 6 others soon after birth. The results were much worse for the 26 cases treated by Braxton Hicks version, 2 of the mothers dying (one from acute anaemia, the other from sepsis) and 9 suffering from puerperal fever. As many as 23 of the 26 infants died during labour, and one died shortly after birth. It should, however, be noted that 10 of the infants were either dead or dying before this form of version was performed. Only in 8 cases was dilatation of the lower segments of the uterus aided by the introduction of a bag, and none of the women thus treated died. In 7 cases Caesarean section was performed, and in every case the lives of both mother and infant were saved. Comparing treatment by Braxton Hicks version with that by Caesarean section, the author remarks that the popularity of the former is on the wane, whereas that of the latter is still growing, and had it been performed more often instead of version her results would have been much better than they were. She also argues that much better results would be obtained in hospital with cases of placenta praevia if general practitioners and midwives would consider haemorrhages during pregnancy as an indication for sending the expectant mother forthwith to a maternity hospital instead of temporizing, infecting the uterus and vagina by internal examinations, and resorting to such measures as the introduction of tampons, which favour sepsis and render the prospects of a sterile Caesarean section comparatively bad.

590. W. BALLHORN (*Arch. f. Gynäk.*, March 14th, 1925, p. 646) remarks that in the treatment of placenta praevia vaginal tamponage is usually ineffective in arresting haemorrhage and increases the danger of infection; its use by midwives and practitioners should be discouraged. Emphasis is laid on the importance of early admission to hospital of the patient, after the minimum of examination and manipulation. In an institution rupture of the membranes in cases of lateral placenta praevia with head or breech presentation and two fingers' dilatation of the os is to be recommended: in the Mainz clinic about nine out of every ten of the living children born at term in placenta praevia

cases are delivered by this treatment. The disadvantage of Braxton Hicks version lies in the high foetal mortality, which must be set against its certain efficacy in stopping bleeding. The use of the intraovular or extraovular dilating bag is sometimes attended by very considerable haemorrhage, is fraught with the risk of cervical tearing (4 per cent. in the author's series), frequently necessitates version after expulsion of the bag, and is attended by considerable foetal mortality and maternal morbidity and mortality. Internal version as the sole treatment has a very limited place, being justifiable only when there is full cervical dilatation. Probably the greatest improvement in maternal and foetal mortality is to be expected from early admission to hospital and extended employment of Caesarean section, transperitoneal and at the same time cervical.

591.

## Kjelland's Forceps.

BRINDEAU and LANTUEJOL (*Gynéc. et Obstét.*, 1925, xi, 3, p. 199) are unable to agree with those who have reported favourably of the obstetric forceps introduced by Kjelland, which has short handles, no axis tractor, a pronounced cephalic curve, and an articulation permitting a gliding movement of one blade over the other. They find that if it is applied to a foetal head outside the pelvis the diameters of the head and superposed blades, regarded as one, are larger than in the case with other commonly used forceps. With a foetal head placed within a rigid metal model of the pelvis, of 10.5 cm. conjugate, they find delivery more difficult with the Kjelland than with other instruments. The special manoeuvre which Kjelland enjoins for application to the transversely placed head in the brim is described by the authors as fraught with danger of rupturing the uterus. Such clinical trials as they have made have not impressed them favourably with the merits of the instrument. They conclude that the mechanical principles on which the instrument is based are such as were discussed and abandoned some years ago by French obstetricians.

## 592. The Foetus after X-ray Treatment of the Ovary.

E. MEINER (*Zentralbl. f. Gynäk.*, March 28th, 1925, p. 682) records the case of a primipara, aged 34, who complained of amenorrhoea and sterility following the birth of her child twenty months before. At three months' interval two small doses of x rays were directed to the ovaries. Six weeks later menstruation returned, and nineteen months later a living, healthy, and well developed child was born. Meiner remarks that foetal deformities are to be feared only when radiation is carried out after conception. H. NAUJOKS (*ibid.*, April 4th, 1925, p. 776) describes the case of a woman who received massive post-operative x radiations for sarcoma of the ovary, two out of three being given in the early months of an unsuspected gestation: the child, born at term, weighed 7 lb., and at the age of 2 showed clear signs of microcephaly and idiocy. Microcephalic changes in the foetus are also described in two cases in which x-ray applications were given during the second month of pregnancy on account of symptoms due to uterine myoma.

## Pathology.

593.

## Pathogenesis of Tetany.

MACDONALD CRITCHLEY (*Arch. Intern. Med.*, January 15th, 1925, p. 100) defines tetany as a condition of peripheral nervous hyperexcitability, characterized by intermittent spasms of the extremities, without loss of consciousness. It may arise either as a disease *sui generis* (idiopathic tetany) or as a complicating factor in the course of other morbid or physiological states. The author suggests that the precipitating cause in all types of tetany is an alteration in nitrogen metabolism, leading to the appearance in the blood stream of highly toxic nitrogenous by-products which are normally excreted as urea or creatin. These toxic substances are said to be probably guanidin or some of its derivatives. The factors regulating the metabolism of nitrogen are extremely numerous, and interference with any one of these is liable to give rise to tetany. Such interferences are parathyroid removal, auto-intoxications, gross changes in the acid base balance, inadequate or unsuitable dietary, the absorption of poisons, conditions of anaemia or conversely a deficiency in carbon dioxide, vitamin deficiency; and, in the tetany of workman, an acute organismal infection of the parathyroids according to Paton and Findlay. Calcium metabolism operates in the neutralization of circulating toxins either by direct combination with them to form innocuous substances or by rendering the tissues less permeable. The appearance in the circulation of toxic nitrogenous by-products will therefore deplete the calcium reserve. The administration of calcium

salts, the withdrawal of blood, or the dilution of the circulating poisons by saline solution alleviate the symptoms of tetany and tend to break the vicious circle that has been formed.

## 594. Functions of the Thymus and the Palatine Tonsil.

G. SALVADORI (*Arch. Ital. di Otol., Rinol. e Laringol.*, January, 1925, p. 1) remarks that the palatine tonsil is considered by some as being merely one of the great class of lymphatic glands which, owing to its position, filters organisms from the throat. Others consider that, whatever its original function, it now acts as a portal of entry for organisms of disease. The tonsil is also described as a member of the haematopoietic system and concerned chiefly with leucocytes or with erythrocytes. It has also been credited with an internal secretion. The thymus, again, has been credited with an internal secretion, and has been regarded as an intermediate link between the haematopoietic system and the lympho-adenoid system. Experimental removal of the thymus in various young animals had no very grave consequences, but it was reported by some writers that the erythrocytes and total haemoglobin were reduced. Other investigators have found that the removal of the thymus rendered frogs more liable to septicaemia. In cats and rabbits removal caused loss of weight and death. In young dogs it was found that changes took place in the osseous system and in calcium metabolism. In many cases a diminution in lymphocytes was noted in thymectomized animals. Salvadori concludes that the tonsil is chiefly a haematopoietic organ, while the thymus subserves two functions—that of controlling osteogenesis and calcium metabolism and that of a haematopoietic. He found that the removal of the tonsils alone in small dogs only caused a slight diminution in red blood cells and a slight rise in white cells. When the thymus was removed there was a very marked diminution in red cells. He thinks that these two organs are concerned with blood formation, and are erythropoietic rather than producers of white cells. The glands appear to act in concert and the removal of either is followed by the regression and atrophy of the other.

## 595. The Cultivation of Tubercle Bacilli.

M. ISABOLINSKY and W. GITOWITSCH (*Zentralbl. f. Bakt.*, March 10th, 1925, p. 241) report some experiments made to determine the most suitable method for the cultivation of tubercle bacilli. With Besredka's fluid medium they had very little success, finding that, possibly owing to the high alkali and lipid content, the bacilli underwent bacteriolysis and became granular. Petroff's gentian-violet egg medium was satisfactory for old acclimatized cultures, but was unsuitable either for primary isolation or for the subculturing of freshly isolated strains. The case was similar with Zeehnwitzer's medium, an egg mixture to which 20 per cent. of glycerin has been added; this had the advantage, however, over Petroff's medium of not drying so rapidly. Glycerin potato media were soon discarded, as the growth was very scanty and soon died out. They describe a new medium prepared as follows: The testicles of oxen are stripped, minced in a machine, and ground into a mash in an electric mill. To two parts of this mash is added one part of fresh bovine serum; the medium is sloped in tubes and sterilized at 90° C. on the first day, and at 80° to 85° C. for half an hour on the three following days. Growth on this medium was abundant; after two to three weeks there was a layer of yellowish-white nodules, which in the case of the human type of bacilli assumed later a rose tint. It is described as being suitable both for primary cultivation of tubercle bacilli from sputum and for continued culture in the laboratory. There is the further advantage that it is cheaper to prepare than egg media.

## 596. Immunization against Diphtheria by Anatoxin.

E. C. PICO (*C. R. Soc. de Biologie*, March 27th, 1925, p. 899) states that the importance of anatoxin in immunization is becoming more evident daily, but that, hitherto, experiments to prove the curative action of this substance in diphtherial infection in the absence of antitoxin have been unsuccessful. If injected twenty-four to forty-eight hours before experimental diphtherial infection of the conjunctiva of a guinea-pig it does not prevent the development of the disease (Zoeller), nor does it have any action if given in local instillations or injected in doses of 0.5 c.c.m. on three or four consecutive days. Pico's experiments have also been completely negative, and he concludes that antitoxic serum therefore must be employed in the treatment of diphtheria. He adds that the prophylactic methods employed against diphtheria owe their efficacy to their ability to produce antitoxin, which serves as an index of the immunity produced.

## Medicine.

### 597. Cerebro-spinal Fever and Chronic Nephritis.

J. SABRAZÈS and O. MASSIAS (*Gaz. hebdomadaire de Médecine*, April 12th, 1923, p. 225) record the case of a woman, aged 25, suffering from cerebro-spinal fever, who was treated by a series of six intrathecal and intramuscular injections of polyvalent antimeningococcus serum. Suppurative arthritis of the right knee developed, and was considerably benefited by intravenous injection of an autogenous vaccine. A relapse of meningitis, however, occurred after the fifth day of intrathecal treatment. The twenty-fifth day of the disease became worse, polyuria ceased, the urine contained 7 grams of albumin, the blood pressure rose, uncontrollable vomiting set in, and a state of uraemia with azotaemia developed. The headache, vomiting, and bilateral choked disc suggested suppurative ophthalmitis. In spite of intravenous injection of hypertonic glucose solution and bleeding the patient had marked azotaemia and died. The oliguria, haematuria, and albuminuria excluded the diagnosis of ophthalmitis in favour of uraemia. The autopsy showed absence of pyoccephalus, a case of the meningitis, and the presence of renal atrophy, especially of the right kidney. Histological examination confirmed the diagnosis of diffuse interstitial and parenchymatous chronic nephritis, with glomerular and intertubular sclerosis.

### 598. Skin Reactions in Disease.

P. VALLERY-RADOT and P. BLAMOUTIER (*Presse Méd.*, March 25th, 1923, p. 385) describe a method of diagnosis and treatment based on the production of anaphylaxis by repeated skin reactions with a specific antigen in such diseases as asthma, hay fever, migraine, urticaria, and eczema. Their technique is as follows. The flexor surface of the forearm, having been disinfected with 90 per cent. alcohol, is then scarified at intervals without drawing blood. On each scarification of about 2 mm. in diameter a drop of decinormal soda solution is placed; then a very small quantity of the required powdered protein is added to each drop except the last. If the protein is in solution this may be applied without using the soda solution. When the sensitizing substance is unknown, various proteins which are the most frequent causes of anaphylaxis should be applied in turn to the scarifications. After an interval of fifteen minutes the series of scarifications is washed with a tampon of cotton-wool and boiled water.

The last scarification is treated with the others. A urticaria-like patch of by a more or less definite zone of erythema and often accompanied by itching. A simple local erythema is not to be regarded as a positive reaction. The authors describe in detail various methods of extracting specific proteins. In asthma various American and European investigators have reported 40 to 48 per cent. of positive reactions, but in many cases they have included hay fever. When an asthmatic knows the nature of the agent that produces his disease this method serves as a control test; when the agent is unknown, a positive reaction cannot be regarded as strictly specific, for many chronic asthmatics react to several different proteins; one female patient reacted to every protein. A positive reaction is, therefore, not a definite proof of sensitization. The authors point out that only when entire removal of the responsible protein or specific desensitization treatment has abolished the attacks can the differential diagnosis be established. They add that this principle applies also to other anaphylactic states, such as spasmodic coryza and urticaria. Animal products, including hair, feathers, and wool, account for the majority of positive reactions, and the common use of these materials in bedding may explain the frequency of nocturnal crises of asthma. In spasmodic coryza the authors obtained only 3 positive reactions among 17 cases, but most striking results were obtained in hay fever: among 26 patients there were 25 positive reactions to various pollens, all these patients reacting to several pollens of the same species. In urticaria and Quincke's oedema a much smaller percentage of positive results was obtained. Among 17 cases of urticaria the authors obtained only 5 positive results (eggs, barley meal, and potato). They had no success in 5 cases of Quincke's oedema. Schloss records 40 positive reactions to food proteins among 53 children suffering from eczema; Scott O'Keefe obtained 41 per cent. of positive reactions in similar cases. White thinks

that 80 per cent. of cases of chronic eczema are due to alimentary sensitization. The authors conclude that it is often sufficient to remove the source of irritation: when this is impossible they recommend desensitization by repeated injection of minute but increasing doses of the specific protein.

### 599.

### Chronic Nephrosis.

R. H. MAJOR and F. C. HELWIG (*Bull. Johns Hopkins Hosp.*, April, 1923, p. 250) point out that while chronic nephrosis has certain clinical features in common with chronic nephritis it is a definite disease entity. Notes are given of a case in a man, aged 34, suffering from dyspnoea, marked oedema, and albuminuria with hyaline casts. The blood showed a marked lipaemia, and an examination of blood proteins gave the ratio of serum albumin to serum globulin as 1:2 instead of the normal 2:1. Microscopic examination of the kidney showed fat droplets in the tubules, interstitial tissue, and glomeruli, and the liver also showed marked lipid infiltration about the central zone of the liver lobule. This lipid material in both the liver and kidney reacted similarly to the special stains. The authors consider that this type of lipid is not a simple cholesterol ester, but probably belongs to the complex phosphatid group in which cholesterol is loosely bound. Chronic nephrosis appears to be primarily a disturbance of metabolism, and the presence in the liver in the authors' case of an intense lipid infiltration similar to that seen in the kidney supports the theory that it is a metabolic disease.

### 600.

### Prophylaxis of Orchitis in Mumps.

V. DE LAVERGNE and P. FLORENTIN (*Bull. Acad. de Méd.*, March 31st, 1923, p. 362) state that the excellent results obtained in the prophylaxis of measles by injection of convalescent serum induced them to apply this method to mumps, especially as Debré and Joannon had already shown that the development of parotitis might be prevented thereby. During a large epidemic of mumps the present authors employed the method in 113 patients. In uncomplicated cases the blood was taken on the fifteenth to the twenty-fifth day, and in cases complicated by orchitis after the inflammation had subsided. The serum was prepared in the usual way and injected subcutaneously in successive doses of 10 c.cm., 15 c.cm., and 20 c.cm. The results were as follows: Of 107 untreated patients 25 developed orchitis and 9 symptoms of meningitis, whereas of 113 treated patients only 5 developed orchitis and 2 meningitis. Moreover, the five cases of orchitis occurred among 85 patients who had only had 35 c.cm., while the remaining 28, who had been given another 20 c.cm., had no orchitis.

## Surgery.

### 601.

### Fat Necrosis of the Breast.

G. KEYNES (*Brit. Journ. Surg.*, April, 1923, p. 663) describes a case of fat necrosis of the breast. The patient was a stout woman with large breasts; a small painful nodule was present in the upper and outer quadrant of the left breast. The nodule was not well defined, the nipple was not retracted, and no enlarged glands were found in the axilla. A diagnosis of carcinoma was made. The operation incision revealed white areas extending from just below the skin into the mammary gland, and surrounded by a zone of infiltration. A frozen section showed large polyhedral cells apparently lying in alveoli. The cells were not quite characteristic of carcinoma, being even larger than the unshrunk cells seen in fresh sections. The diagnosis was regarded as confirmed, and the operation was performed. Subsequent examination showed necrosis in fatty areas, and infiltration of the necrosed tissue by leucocytes; there were some large polyhedral cells at the periphery, and some embryonic fat cells were present. Scattered through the lesion were multinucleated giant cells, characteristic of the lesion; the nuclei of these were centrally placed. No traces of a haematoma were found, but the author thinks there is little doubt that the condition was due to trauma and comparable with the other cases recorded in which it has been produced by direct infusions. The author regards this as a case of fat necrosis, and emphasizes the diagnostic importance of a history of injury, the naked-eye observation of the chalky white necrosed areas, and the microscopic appearances.

602. **Ligature of the Hypogastric Arteries.**

R. FINALY (*Nederl. Tijdschr. v. Geneesk.*, March 7th, 1925, p. 1115), who records two illustrative cases, states that Nikolsky in 1912 collected 192 cases from the literature of ligature of the hypogastric arteries, the indications being as follows: aneurysm of the gluteal artery (32 cases), injury to the gluteal artery (3 cases), enlarged prostate (7 cases), extirpation of carcinoma of the rectum (22 cases), palliative operation for carcinoma of the uterus (64 cases), and removal of carcinoma of the uterus (64 cases). Nikolsky had also 48 cases of his own, including 45 for removal of cancer of the uterus, in which he had never observed any bad results following ligature of the hypogastric arteries. In a subsequent paper he reported 10 cases of unilateral and 35 of bilateral ligature of the hypogastric artery in which no sequelae had been observed. Flörcken (1916), Wieting (1918), and Brunzel (1919) all recommend ligature of these arteries as an excellent method for controlling haemorrhage from the superior and inferior gluteal arteries, and Tasso Asteriades (1924) has also collected 41 cases from the literature as well as one of his own in which this procedure caused a remarkable and immediate cessation of haemorrhage in inoperable cancer of the uterus. In spite of these favourable reports the method is not free from danger. Meyer's patient, a man of 65, died suddenly from an unknown cause two days after the operation; no autopsy was permitted. Offergeld's patient, a woman aged 57, in whom the arteries had been ligatured for inoperable cancer of the uterus, died of heart failure three days after the operation. The autopsy showed thrombosis of the common iliac artery and fatty degeneration of the myocardium. Finaly's first patient was a man, aged 57, in whom ligature of both hypogastric arteries was performed for carcinoma of the rectum. A few days later gangrene of the scrotum developed and gradually extended over the perineum. Death occurred sixteen days after the operation; there was no autopsy. The second case was that of a woman, aged 74, in whom the arteries were ligatured before Wertheim's operation; necrosis of the vesical mucosa developed, but recovery followed.

603. **Excision of the Rectum.**

E. VILLARD and A. RICARD (*Lyon Chir.*, March-April, 1925, p. 129) describe in detail the technique they have devised for radical removal of the rectum in cases of carcinoma. The essential feature in their operation is the retention of an anus in the natural position, and under voluntary control, by preservation of the sphincter. In the first step of the operation the abdomen is opened by a median incision below the umbilicus. The character of the growth, its fixity, and the condition of the glands are first investigated. If favourable for removal the lower portion of the sigmoid is mobilized, care being taken to preserve the ureters intact. The bowel is freed, the mesentery and vessels being divided, and the mobilized portion of bowel and growth pushed down into the pelvis. After peritonization of all raw surfaces the abdominal incision is closed. The growth is then approached from the rectum. A circular incision is made round the anus, and after dilatation of the sphincter it is carefully separated from the termination of the bowel. Through this space the rectum is easily freed and the mobilized portion brought down through the wound. The bowel is divided well above the growth and the new anus sutured in position by a continuous catgut suture. The anus is packed with gauze for a short time and tubes are placed in the ischio-rectal fossae. In ten patients treated by this method three are dead—an operative mortality of 30 per cent. Three other patients show no evidence of recurrence after three years, the functional result of the operation is excellent, and the sphincter functions normally.

604. **The Predisposing Causes of Renal Calculi.**

P. BULL (*Norsk Mag. f. Laegevidenskab.*, May, 1925, p. 429) gives an account of 53 cases operated on by him for calculi of the kidneys and ureters. In as many as 11 cases the affected kidney was found to be displaced downwards, in 4 cases there was an S-shaped ureter, and in 2 the lower opening of the ureter was abnormally situated. Abnormalities such as these may promote the formation of calculi, not only by facilitating retention of urine in the renal pelvis, but also by facilitating infection of the urinary passages. In 2 cases trauma had evidently played a part in the development of renal calculi by favouring infection. In one of these cases the pelvis had been fractured and the urethra torn, with the result that stenosis and secondary infection of the urinary passages occurred. In the second case severe injuries included rupture of the left kidney, in which, four years later, calculi were found in association with pyonephrosis. In 1 case there was a history of catarrh of the bladder, but renal calculi.

1155 B

**Therapeutics.**605. **Vaccine Treatment of Whooping-cough.**

O. A. ALDRICH (*Amer. Journ. Dis. Child.*, April, 1925, p. 4) records his observations on 65 cases of whooping-cough treated with vaccine and the results of vaccine prophylaxis in 17 cases. The prophylactic treatment consisted of three subcutaneous injections on alternate days of a glycerol vaccine containing the Bordet-Gengou bacillus only. The doses were one of two billion and two of four billion bacilli, without regard to the age of the child. Patients with a suggestive cough, especially with a history of exposure to the disease, had three or four injections of the same vaccine on alternate days in doses of two, four, six, or sometimes eight to ten billion. Patients treated after the onset of symptoms had slightly milder and shorter attack than usual. There were no complications except the usual bronchitis, and there was evidence that in some the disease aborted in the catarrhal stage. As regards the prophylactic value of the vaccine there was definite evidence that some cases were prevented, though in the absence of control the percentages could not be estimated. Only four of the seventeen individuals given prophylactic treatment developed pertussis. As regards the course of the disease in the treated cases, the average duration was about six weeks with definite and lasting improvement beginning less than four weeks from the onset. The duration of the disease and the length of time before improvement were approximately the same regardless of the time of treatment, but the patient treated later had slightly severer attacks.

606. F. VAN DER ZANDE (*Nederl. Tijdschr. v. Geneesk.*, April 4th, 1925, p. 1575) states that since June, 1922, he has treated all his cases of pertussis exclusively by vaccine therapy. The treatment consisted in injection of the contents of four ampoules, each holding 1 c.c.m., the first containing 1,000 million bacilli, the second 2,000 million, and the third and fourth 3,000 million. The injections were given subcutaneously at intervals of three days, beginning with the smallest dose. In some cases a fifth injection was given of 1 c.c.m., containing 5 million bacilli. The following criteria were used in estimating the effect of the vaccine: (1) diminution in the number of the paroxysms; (2) diminution in the violence of the attacks; (3) shortening of the duration of the disease. In forty-one cases the results were very good—that is to say that after four injections no definite paroxysm occurred and there was little or no cough. In five patients the results were satisfactory, as shown by diminution in the number of the paroxysms, though the duration of the disease was not shortened nor the violence of the attacks mitigated. In six cases the treatment was a failure. In successful cases considerable improvement was obtained after the second injection; sometimes it was delayed until after the third, but rarely until after the fourth. No bad effects were observed. The injections were well borne, even by very young infants, and no fever, restlessness, or infiltration developed. Failure of vaccine treatment in pertussis is attributed by Luttinger to the use of too old a vaccine or to the injections having been given intramuscularly instead of subcutaneously. Van der Zande, however, is of opinion that the failures are due to there being two groups of pertussis bacilli, and that a vaccine may contain only one group when the disease is due to the bacilli of the other group. In future, therefore, pertussis vaccine should combine both groups of bacilli.

607. **Strophanthus in Heart Disease.**

L. STORDEUR (*Le Scalpel*, March 21st, 1925, p. 253), comparing strophanthus with digitalis, states that although there are differences in their effect in cardiac therapy, these differences have been exaggerated. Strophanthus, especially if given intravenously, acts more quickly on the failing heart than digitalis, and sometimes, as in alternating pulse, will relieve when digitalis is powerless; so also in tachycardia and in cardiac conditions complicated by pyrexia. It may also be used to intensify the action of digitalis and be given either simultaneously or successively. The author then describes in detail the action of strophanthus in various cardiac conditions. It should not be given when serious kidney disease is present for fear of a cumulative effect, nor in cases where a secondary infective endocarditis has supervened on a valvular lesion; when the myocardium is much degenerated or sclerosed strophanthus is dangerous. It is better avoided where thrombosis of the heart is suspected, and if given in full doses after digitalis a period of three days should intervene. Nausea and vomiting indicate that the drug should be discontinued. Stordeur finds that the best results are obtained by intravenous injection in doses of 1/4 to 1/2 mg. a day. It is very irritating to the cellular tissue, so that care must be observed in injection.

## Radiology and Electrology.

### 608. A New Method of Examining the Gall Bladder Radiologically.

G. SABATINI and E. MILANI (*Il Policlinico*, May 4th, 1925, p. 623), recalling the opacity of bromine salts to the x-rays, and the fact that they are eliminated by the liver, have found that after administering the salts by the mouth a picture of the gall bladder might be obtained. The preparation of the patient is important. In the early morning an egg and some soup is given, at 2 p.m. a dose of castor oil, at 7 p.m. a cup of milk, and after that no food or fluid of any kind. Still later a saline enema is given, and early next morning 20 grams of sodium bromide and strontium bromide in 100 c.cm. of water. The radiogram is taken five or six hours later. By this method the gall bladder was demonstrated in 60 per cent. of normal bladders and in 80 per cent. where cholecystitis was present. In several cases when the gall bladder could not be seen by ordinary methods a distinct shadow appeared after the bromide treatment. The authors give eight reproductions of radiograms taken by this method.

### 609. X-Ray Examination of the Male Urethra.

E. H. P. CAVE and G. L. S. KOHNSTAM (*Brit. Journ. Radiol.*, April, 1925, p. 121) consider that by the employment of a standard technique in urethrography reliable information may be obtained about urethral and prostatic conditions. Previous routine preparation of the patient is said to be unnecessary. The most satisfactory medium is lipiodol, either concentrated or diluted (for economical reasons) with four times its volume of sterile paraffin, such dilution in no way materially reducing its opacity or viscosity. The postero-anterior position, with the patient lying on the plate with the tube centred over the bulb of the urethra, is better than the antero-posterior position, in which the shape of the base of the bladder may be distorted through falling posteriorly on to a full rectum. A routine examination should also include an oblique lateral view with the tube centred over a point one inch below the mid point of Poupart's ligament. The authors used gas tubes of 4½-inch spark-gap and passing 5 milliamperes with an average exposure of two to three seconds for the postero-anterior view, and four to six seconds for the oblique. Intensifying screens were used; the distance of the anticathode from the film in the postero-anterior view was 20 inches and in the oblique 24 inches. They point out the importance of ensuring a continuous flow under constant pressure when injecting the opaque material, and recommend a pressure flask regulated by hand bellows, a mercury manometer, and a glass urethral nozzle. Four illustrative radiograms are supplied.

### 610. Electrical Treatment of Exophthalmic Goitre.

STEPHEN PORTRET and YVES HELIE (*Journ. de Radiol. et d'Electrol.*, February, 1925, p. 55) point out that in exophthalmic goitre two factors appear to be established incontestably: (1) the thyroid dystrophy in a neuropathic patient predisposes to the development of exophthalmic goitre; (2) on the other hand, there is an interference with thyroid function, due to disturbance of other endocrine glands, associated in the majority of cases with lesions of the sympathetic. The authors state that French surgeons have abandoned surgical treatment on account of the high mortality rate, the disfiguring scars, and the frequent failures, and add that the only medicinal treatment which has given generally satisfactory results is pituitary or ovarian opotherapy. They strongly condemn thyroid medication, which often aggravates the disease. Radiotherapy has frequently failed to relieve the exophthalmos, although some reduction in the size of the thyroid gland has been noted in many cases following an improvement in the general and cardiac symptoms. The authors record ten cases in which electrical treatment produced lasting improvement. They prefer a continuous current of from 60 to 110 volts; they place a rheostat in the circuit, and by a gradual elevation of the voltage avoid any shock—an important consideration in the case of these very nervous patients. The negative (active) electrode, a large flat sponge moistened in tepid water, is placed over the anterior surface of the neck; the smaller positive electrode is placed between the shoulders. At first the strength of the current should not exceed 5 to 7 milliamperes, the duration of the sitting being ten minutes. If the patient's skin shows no sign of irritation a current of 15 milliamperes for twenty minutes may be well borne subsequently. Patients who have previously received x-ray treatment are often more susceptible to electrical skin irritation. After five treatments a week, until twenty treatments have been given, there should be an interval of a month, following which a second series of treatments is often required, and in some cases a third course may be necessary,

the treatment lasting from eight to ten months. There may be erythema persisting for forty-eight hours, or even vesication or desquamation requiring application of zinc ointment. The authors report 30 cases of treatment by the galvanic current alone or by the constant and interrupted current. In every case lasting improvement followed, even in the 10 cases where no improvement had resulted from irradiation. The authors conclude that electrical treatment has been undeservedly neglected. In their first 20 cases, 18 improved both generally and in regard to nervous symptoms. The thyroid tumour diminished in 97 per cent., tachycardia and arrhythmia in 75.8 per cent., tremors in 81.2 per cent., and exophthalmos in 45.2 per cent. They add that electrical treatment is perfectly safe and appears to regulate thyroid dystrophy and glandular secretion, and to act as a sedative to the sympathetic system; it should be tried before any other treatment has been given.

## Obstetrics and Gynaecology.

### 611. Extraction of the After-coming Head.

R. COSTA (*Annali di Ostet. e Ginecol.*, March 31st, 1925, p. 229), who has already devised a hook to be used when the foetus is dead for the extraction of the after-coming head in breech deliveries, now describes a "flat hook" which is equally effective and which he has found can be used safely in the case of a living child. The instrument is 35 cm. long, has a winged handle for traction, and a slight pelvic curve; it is curved to a right angle towards the end, the portion beyond this angle being flattened and measuring 3.5 cm. in length and 2 cm. in breadth. Covered with India-rubber this end is introduced into the mouth and held in position with the index finger of one hand, while the other hand pulls on the handle. Extraction by this means is found easier than by manual manœuvres alone or forceps delivery; it is also speedier, and therefore may tend to diminish foetal mortality. The advantages claimed are that pressure is exercised deep within the month on the ascending ramus of the lower jaw, so that—in contrast with flexion by the finger alone—no portion of the flexing force is spent in opening the mouth rather than flexing the head. Only a minimum amount of traction need be exerted on the breech and neck.

### 612. Fixation of the Anterior Arm in Podalic Version.

ACCORDING to ROUËL and JAHIER (*Bull. Soc. de Gynéc. et d'Obstet. de Paris*, 1925, 3, p. 214), fixation of the anterior arm, which has long been recommended in delivery by podalic version in transverse presentations, is a manœuvre which may also be employed with advantage in cases in which it is decided to turn a cephalic into a podalic presentation before delivery. The accoucheur's hand (the left when the occiput is to the left of the pelvis, otherwise the right) holding a tape about 3 feet long and 1½ inch wide, after pushing the head upwards, grasps the band of the anterior foetal arm and passes the tape around the wrist. This can usually be performed in the uterus, but if the foetal arm has to be drawn into the vagina its subsequent ascent presents no difficulty. The ends of the tape are held by an assistant, and a foot or the feet are brought down in the usual way. Just before the anterior hip appears at the vulva, traction on the tape and on the breech delivers the foetal abdomen, followed by the thorax and anterior arm. The advantages claimed are that: (1) difficulties arising from extension of the after-coming arm are prevented; (2) the hisacroamial diameter engages in a position of anterior asymmetrism; (3) during delivery of the posterior arm a diameter of 8 cm. (extending from the acromion to the opposite side of the neck) engages instead of the hisacroamial diameter of 12.5 cm.; (4) the delivery of the after-coming head between the two arms is avoided.

### 613. Localized Abdominal Suppuration in Women.

E. MARTIN (*Zentralbl. f. Gynäk.*, April 25th, 1925, p. 898) agrees with Bumm that in all cases of peritoneal suppuration the healthy peritoneum must be kept out from the inflamed area by suturing over it an adjacent loop of intestine, but adds that this treatment has not been generally approved in practice. Martin records two cases that confirm Bumm's views. In the first case, during ennetage the lateral uterine wall was perforated and the vessels of the broad ligament and the peritoneum torn. A localized peritonitis followed, and laparotomy was performed; the broad ligament was plugged to arrest venous haemorrhage, and an adjacent loop of small intestine was sutured over the infected laceration, completely occluding that area. Recovery was uninterrupted and the bowels acted regularly; later a ventral hernia developed, and finally complete intestinal obstruction occurred. Two years after the first operation the hernial sac was

opened: there were no signs of peritonitis, the loop of intestine was quite free, and all adhesions had been absorbed, leaving an easily recognizable scar in the posterior peritoneal surface of the broad ligament. It was impossible to determine the duration of the adhesions resulting from the suturing of the intestinal loop over the lacerated wound of the broad ligament. In the second case the patient developed an acute metastatic pyosalpinx during the latter part of her puerperium: laparotomy was performed, and the peritoneum in the vicinity of the inflamed tube was seen to be slightly reddened. The infected area was roofed over by suturing an adjacent loop of small intestine to the surrounding healthy peritoneum. In this case also a ventral hernia developed, and about two years later another operation was performed. Slight local reddening of the peritoneum was present, but the intestinal loop was entirely free and there were no adhesions. The patient had not suffered from constipation after the primary operation. Martin insists that Bumm's method securely shuts off the healthy peritoneum during and after the acute stage of inflammation, and also permits the performance of a secondary operation in more favourable circumstances. Martin lays stress on the importance of keeping these patients under occasional observation for a prolonged period.

#### 614. Paget's Disease of Mammary Origin.

HICKEL (*Bull. Soc. Franç. de Derm. et de Syph.*, March, 1925, p. 29) records a case of Paget's disease in a woman, aged 55, the mother of five children, all of whom she had suckled, who six months previously had developed an oozing erosion of the left nipple which was regarded at first as eczema. Three weeks before admission to hospital she had noticed a swelling in the substance of the left breast. On examination a diagnosis was made of cancer of the breast with glandular metastases and invasion of the lactiferous ducts; this was confirmed after amputation of the breast. The lesion of the areola was identical with that described in Paget's disease, but appeared to be due to a secondary invasion of the epidermis by cancer cells. The case therefore confirmed the view of those writers who hold that Paget's disease should not be regarded as an independent affection, but as a secondary phenomenon in the course of mammary cancer, the remarkable feature of the condition being that the cancer cells affect the epidermis only without involving the dermis. In answer to the objection that Paget's disease often lasts for years without the slightest trace of a primary growth in the breast Hickel remarks that some mammary tumours have a very slow growth in spite of early invasion of the lactiferous ducts and may remain latent for a long period, the only manifestation being the cutaneous lesion. M. B. Schmidt in 1912 reported the case of a woman, aged 65, in whom Paget's disease had involved the whole surface of the breast in the course of eight years without the slightest tumour being detected in the substance of the breast. On amputation of the breast, however, a small cancerous nodule was found in its substance, with invasion of the lactiferous ducts. The apparent absence of any mammary tumour is therefore not an argument in favour of the independent existence of Paget's disease.

### Pathology.

#### 615. Variations in Pneumococci during Culture.

H. A. REIMANN (*Journ. Exper. Med.*, May, 1925, p. 587) has confirmed and extended F. Griffith's work on the dissociation of the pneumococcus into two varieties—a rough and a smooth. A Type I strain was transferred 240 times in plain broth; on agar plates made from the last subculture two forms of colonies were seen—a flat, thin, greenish, and translucent variety, and a heaped-up, thicker, more opaque and less greenish variety. The organisms composing these different colonies were found to have important points of distinction. The first or smooth (S) type were specific, in that they were agglutinated solely by a Type I antipneumococcal serum; the second or rough (R) type were non-specific, being agglutinated by all three types of serum. Further, the S type was highly virulent to mice, killing them in a dose of 0.0000001 c.c.m. given intraperitoneally; the R type was avirulent, failing to kill even in a dose of 2 c.c.m. The same dissociation into the S and the R types was produced much more rapidly by growing the organism in broth containing dilute bile. In this medium the two types appeared in the third transfer; after nine transfers the R type completely ousted the S type, which failed to develop any further. Similarly, in broth containing 1 per cent. of immune Type I serum the dissociation occurred rapidly—in the fifth transfer—and the S type was replaced completely by the R type after nine transfers. Reimann states that the two types can

easily be separated from each other by animal passage. As the S type is highly virulent, it multiplies in the body of the mouse and is found in large numbers in the heart's blood; the R type, on the other hand, though present in the blood for about four hours, fails to undergo further development, so that after six hours it is no longer recoverable from the heart's blood. The R type seems to be a derivative variety of the S type. When a pure S type is cultivated *in vitro*, after a time it begins to throw off R varieties; an R type, however, never reverts to the S type, no matter how long it is subcultured. Not even after passage through mice—the blood being taken four hours after injection—is there any reversion to the S type nor any increase in virulence.

#### 616. The Functions of the Spleen.

A. BOLAFFI (*Arch. di Patolog. e Clin. Med.*, February, 1925, p. 1) ascribes to the spleen the following functions. (1) It gives rise to cells of lymphoid type, and perhaps also to blood platelets. The evidence for this latter statement is, chiefly, that in the cells of the splenic pulp intact platelets may be found, and that in the embryo platelets are found in these cells before the appearance of megacaryocytes—the cells which are usually responsible for the genesis of the platelets. (2) It destroys red and white blood corpuscles and platelets whenever, from age, toxic influences, or congenital weakness, they depart from their normal structure. In certain diseases, such as haemolytic jaundice—congenital or acquired—and haemolytic splenomegaly, this destructive action of the spleen is increased, and probably has some causal relation to the disease. (3) During a certain period of intra-uterine life the spleen plays a part in the formation of blood cells. In this it merely acts in conjunction with the liver, and with the perivascular tissue of such organs as the lymph glands in assuming a haemopoietic function; as the bone marrow develops this function diminishes steadily till by birth it has nearly ceased. This haemopoietic capacity may be resumed later; such a myeloid transformation has been noted in many conditions, including scariatal and streptococcal infections, congenital syphilis, pernicious anaemia, tumours of the bone marrow, and myeloid leukaemia. An example of such a transformation is described by the author; it occurred in a soldier suffering from malaria and amoebic dysentery. (4) It regulates the metabolism of iron in the body in two ways: it breaks down red blood cells, thus liberating the haemoglobin, and it accumulates and prepares the iron for its subsequent manufacture into haemoglobin. These two activities are concurrent. (5) In the splenic anaemia of adults and in Banti's disease this organ is partly responsible for the production of the anaemia: in these diseases there is diminution in the red and white corpuscles and a low colour index. These changes are not due to changes in the bone marrow, which is apparently normal, nor to increased haemolysis, for all signs of blood destruction are lacking. It is suggested that in some way the spleen may interfere with the normal rate of passage of the blood cells from the bone marrow into the circulation. (6) It influences, and appears to regulate, the haemopoietic activity of the bone marrow: knowledge of this endocrine function is still very scanty. The increase of red cells following removal of the spleen is held to be due to the loss of the controlling influence of the spleen on the bone marrow, which therefore passes into a condition of hyperactivity.

#### 617. Etiology of Pernicious Anaemia.

B. S. CORNELL (*Journ. Canadian Med. Assoc.*, January, 1925, p. 26) considers the etiology of Addisonian anaemia, and reports a series of experiments. The author agrees with those authorities who regard pernicious anaemia as a definite pathological and clinical entity. He reviews the symptoms of the disease, and lays stress on the intestinal and nerve conditions being part of a single toxic infection. In the blood picture macrocytes are considered to be the most valuable diagnostic feature. From his own experiments he concludes that there is no evidence of any constant haemolytic substance in pernicious anaemia stools. Cornell extended Hexter's work and transplanted *B. welchii* into the duodenum of dogs, observing transient changes suggestive of pernicious anaemia. It has also been shown that *B. welchii* can be so introduced without gangrene and but little gas formation. The animals show evidence of a chronic infection with a fall in the haemoglobin and red cell count, together with a colour index of 1 or higher. In the case of the rabbit the blood picture shows the presence of many microcytes with some macrocytes soon after intrasplenic injections of *B. welchii*. The author considers the phenomenon of anisocytosis to be directly due to the action of the bacillary toxin on the red cells. While stating that his experiments have no proved relationship to pernicious anaemia, Cornell urges further investigation on these lines together with systematic search for *B. welchii* at autopsies.

# EPITOME OF CURRENT MEDICAL LITERATURE.

## Medicine.

### 618. Acute Articular Rheumatism and Tuberculosis.

NOVÉ-JOSSERAND (*Journ. de Méd. de Lyon*, April 20th, 1925, p. 251) states that the diagnosis between acute tuberculous arthritis and articular rheumatism will be assisted by careful inquiry into the patient's antecedents, the efficacy of sodium salicylate, very early skiagraphy, and "Jossierand's sign," which is the occurrence of a loud ringing systolic sound in the pulmonary area, combined with a rasping vibration like a very short diastolic thrill. The author describes two cases. The first patient, a youth aged 19, who had grown rapidly at the age of puberty, had a sudden attack of general malaise and shivering. The tonsils were very red and swollen but without exudate. A few days later severe pain was felt in the knees, feet, elbows, and hands, the temperature being 104°. The tonsillitis persisted and the left tonsil was incised without benefit. The knees were very swollen and extremely painful, and the patient sweated profusely. Salicylates and aspirin relieved the pain but had no definite effect on the temperature, which oscillated between 101° and 103°. The heart, lungs, and kidneys appeared to be normal. No skiagrams were taken. The patient was seriously ill for six weeks, after which the temperature fell and the poly-articular synovitis disappeared. Fourteen months after the first illness he had a second attack, but at this time signs of consolidation at the left apex were found which were confirmed by a skiagram, and enlarged glands found at the hilum. The patient died of acute bilateral pulmonary tuberculosis twenty-one months after the first and seven months after the second attack of "rheumatism." The second patient, a man aged 25, after repeated attacks of bronchitis in childhood and a dry pleurisy at the age of 12, had served in the army without illness. He then had a severe sore throat and polyarticular pains, similar in all respects to those of the first patient. Salicylates gave only moderate relief. About the tenth day, when the tonsillitis and arthritis were improving, a slight weakening of the first sound was heard at the apex with accentuation of the pulmonary second sound. No abnormal physical signs in the lungs were discovered, but a radiological examination showed enlarged glands at each hilum. The patient was sent to a mountain sanatorium for six months and made a complete recovery, a later skiagram showing no enlargement of the peribronchial glands. Nové-Jossierand does not consider that these are cases in which an attack of acute rheumatism lit up a quiescent tuberculosis. In the first case he learned, after the patient's death, that his grandfather, aunt, and sister had all died from tuberculosis. Earlier, in both cases, the effect of salicylates was much less definite than in acute rheumatism. He relies on Jossierand's sign as a valuable aid to differential diagnosis, and adds that repeated radiographic examination of the lungs should never be omitted.

### 619. The Effect of Pertussis on the Heart.

P. V. LEDBETTER and P. D. WHITE (*Journ. Amer. Med. Assoc.*, April 4th, 1925, p. 1022) review the literature and report their observations on 232 cases of pertussis observed at the Boston Children's Hospital and Massachusetts General Hospital. The shortest period of observation was one month and the longest seven years. They found that circulatory failure did not occur, though the paroxysms undoubtedly produced a temporary strain, particularly on the right side of the heart. No evidence of permanent damage to the heart could be found in any of the 232 cases, although one child had endocarditis and another congenital morbus cordis before infection.

### 620. Influence of Posture on the Emptying of the Stomach.

P. M. SANDER (*Massachusetts Laeger*, April 16th, 1925, p. 396) shows that when a person lies on the left side the emptying of the stomach is much more rapid than when he lies on the right side. The thirty-six persons he examined were patients treated in hospital for diseases not affecting the stomach. They were given a bulky opaque test meal, and were made to lie first on the right side and, some days later, on the left side until x-ray examinations, repeated every half-hour or hour, showed that the stomach was completely empty or contained only traces of the meal. When the patients lay on the right side the stomach was almost invariably emptied within three and a half hours. When they lay on the left side there was at

first a fairly rapid emptying of the stomach, but when a small portion of the meal had been discharged there was an interval of about two hours during which there was practically no change. This delay was probably due to the action of the force of gravity. In most cases the time taken by the stomach to empty itself was from two to two and a half hours longer when the patient lay on the left side than when he lay on the right. In some cases the difference in the times was from three to four hours. Only in two cases did the stomach empty itself more slowly in the right than in the left-sided posture. The delay was due in one case to menstruation and in the other to psychic depression. Sander believes that by adopting the right-sided posture a patient may hasten the evacuation of his stomach.

### 621. Typhoid Fever in Early Infancy.

M. MALLARDI (*La Pediatria*, April 15th, 1925, p. 413) gives details of 12 cases of typhoid in children under 2 years of age. He says that although not common typhoid is more frequent in young children than is generally recognized. Of his 12 patients 3 who were not treated with vaccines died. The author does not approve the calomel treatment, nor quinine. He accepts the modern view as to a more liberal diet, and thinks it should not be restricted to milk, but, if the children are old enough, should be mixed. If the first Widal test is negative another should be made.

### 622. Concurrent Varicella and Herpes Zoster.

P. GAUTIER and R. PEYROT (*Arch. de méd. des enf.*, May, 1925, p. 306) refer to the case recently reported by Aviraguer, Huber, and Dayras (see *Epitome*, May 9th, 1925, para. 465) of the simultaneous occurrence of varicella and herpes zoster, and record a case in a girl, aged 5, who, in addition to a typical eruption of varicella, presented herpes zoster in the region of the left scialic nerve. The present authors, like Comby, maintain that any eruptive fever may prepare the soil for herpes zoster, but that the latter, which is essentially a neuritis, may be produced by a variety of factors. They add that although some cases at first sight appear to prove the identity of the two affections, and in spite of the serological tests of Netter and Urbain, the fact that varicella produces no immunity to zoster justifies the conclusion that zoster and varicella are two distinct diseases. The simultaneous occurrence of the two affections in the authors' patient, as in other cases on record, should be regarded merely as an accidental association, like that sometimes existing between varicella and measles, or measles and zoster.

## Surgery.

### 623. Congenital Patellar Dislocation.

G. DENCKS (*Zentralbl. f. Chir.*, May 9th, 1925, p. 1010) observes that the comparatively rare condition of congenital patellar dislocation constitutes so serious a disability that, when the patella cannot be replaced by manipulation, a somewhat severe operation is justifiable. Dencks's first patient was a man, aged 20, with a congenital dislocation of the left patella which caused the knee to give way in standing or walking; there was severe pain in the knee after exertion. The patient also had a congenital subluxation of the head of the right radius, a definite left genu valgum, and the patella lay on the outer aspect of the lateral epicondyle of the femur. The tibial tuberosity was in the normal position, but the ligamentum patellae was inserted at its outer side, forming a ridge at an obtuse angle with the tibial axis. His mother had a similar abnormality of the left radius. A fixation apparatus was applied without result. Dencks performed Krogus's plastic operation. Long parallel incisions were made over the inner and outer borders of the joint, the lower ends being united by a transverse incision below the tibial tuberosity, and exposing the quadriceps tendon and patellar ligament. A flap was reflected containing the anterior portion of the capsular ligament, with a triangular resection of the synovial membrane over the condyles of the femur. A block of bone at the site of the insertion of the patellar ligament was then resected from the outer tuberosity of the tibia, and the patella, freed from its lateral attachments, was reflected with this. The internal tuberosity of the tibia above and to the inner side of the tubercle was then chiselled away to permit of the insertion of the bony attachment of the patellar ligament. The edges of the triangular incision of

the synovial membrane were sutured to the raw edges of the patellar flap and the capsular ligament was sutured over the patella. The joint was fixed by a plaster-of-Paris bandage, and passive movements were commenced four weeks later. In six months the joint could be flexed to 75 degrees, the patient was free from pain, and could walk and engage in boxing. About nineteen months later the patient fell downstairs on his left knee, and for some time afterwards he had severe pain in the joint, but ultimately the mobility was unimpaired. Deneks subsequently operated upon a boy of 13 who had a double congenital patellar luxation; healing was delayed by necrosis of the skin edges, and the ultimate result was unsatisfactory. Deneks observes that the treatment of these cases cannot yet be regarded as definitely settled, and hesitates to give more than a guarded prognosis when advising operation.

#### 624. Pre-operative Treatment for Graves's Disease.

A. KREECKE (*Zentralbl. f. Chir.*, April 18th, 1925, p. 866) states that according to Hildebrand the mortality from operations by skilled surgeons for Graves's disease is about 3 to 4 per cent. Hildebrand himself had 24 deaths among 666 operations, or a mortality of 3.6 per cent.; and the mortality of unpublished cases is doubtless much higher. Down to 1918 Kreecke had had 10 fatal cases among 80 operations, or a mortality of 12.5 per cent., but since 1919 out of 46 operations only 2, or 4.3 per cent., had ended fatally. He attributes this improvement in his mortality rate to the following pre-operative treatment. Every patient is made to rest in bed for eight to fourteen days before the operation and to avoid any severe physical exertion or excitement. The rapid action of the heart is, he finds, best checked by an ice-bag, cold compresses, or Lector's tubes. Kreecke has almost entirely abandoned the use of cardiac tonics such as preparations of digitals, but has found that the usual sedatives and hypnotics are much more suitable. On the supposition that the other endocrine glands, especially the thymus, are often responsible for the unfavourable issue of the operation he subjects all cases to irradiation of the thymus, which is performed four or five times at intervals of three or four weeks before the operation. More recently he has also employed irradiation of the suprarenals at intervals of three weeks. The duration of the rest in bed before operation is usually a fortnight, but may be shorter when the heart has been quiet for some days. The patient is not informed of the date of the operation until an hour before it is performed. Ether is the anæsthetic used. In patients whose pulse is below 60, goitre is usually performed on both sides at one time, but if the pulse is constantly above 110, only one side should be dealt with at one operation. Patients who show considerable psychological excitement even after rest treatment and in whom the pulse is 120 or more should not undergo operation. Most of the fatalities which Kreecke has seen were due to neglect of this rule.

#### 625. Renal Tumours in Children.

J. C. SCHIPPERS (*Acta Paediatrica*, April 15th, 1925, p. 141) discusses renal tumours in children, and draws attention to the necessity for careful routine examination of the renal regions of all children, since in the earlier stages these tumours can be removed surgically. He had prognosis that has hitherto been attached to them is, he believes, due to the fact that the surgeon is not called in while the tumour is operable. In some cases these tumours are of pre-natal origin. They generally become manifest before the age of 5; they grow rapidly and to a very great size; they produce metastases only in the later stages and cause death in 90 per cent. of them are unilateral. The tumour consists of embryonic sarcoma round or spindle-shaped cells. Other elements appearing in variable quantities are smooth muscle fibres, cartilage, fatty and bony tissues, and epithelial cells. Schippers deals briefly with the clinical diagnosis, pointing out that the larger tumours are characterized by their lateral position between the costal arch and the iliac crest. The diagnosis is established finally by laparotomy. Examination may be of service. he thinks, very inadvisable. He gives abbreviated clinical details of twelve cases and concludes that the success of nephrectomy is most certain when the operation is performed at a very early period when no adhesions have been formed and the tumour is small. Local anaesthesia has been recommended by Deming, since it is believed that death has in many cases been due to general narcosis. Before the operation the lungs and skeleton should be carefully investigated to exclude the absence of metastases. Treatment by x-rays has also been recommended, but the evidence of its value is at present inadequate; Schippers thinks it may be preferably combined with surgical treatment.

## Therapeutics.

626.

#### Dihydroxyacetone in Diabetes.

I. M. RABINOWITCH, ALTHEA B. FRITH, and ELEANOR V. BAZIN (*Canadian Med. Assoc. Journ.*, April, 1925, p. 374) record observations upon the use of dihydroxyacetone in the treatment of diabetes mellitus. The substance is a ketotriose, unstable in alkaline media, readily oxidized, and nontoxic in a dosage of 50 to 100 grams by the mouth. Glycogen storage in the liver was found to be greater for dihydroxyacetone than for glucose, and a lowering of the blood sugar followed its administration; hyperglycaemia resulted only in severe cases, and then in less marked degree than when glucose had been given. In normal persons a slight increase in the blood sugar similar to that following glucose was seen one hour after the oral administration of 50 grams of dihydroxyacetone. The blood sugar then decreased in amount and after three hours remained below the level noted in the post-absorptive state, the threshold being thus apparently lower than that for glucose. In diabetes the excretion of sugar was greater and the hyperglycaemia more marked and persistent after glucose than after dihydroxyacetone. In four untreated diabetics blood sugar time curves showed a marked degree of hyperglycaemia and glycosuria in the post-absorptive state. After the administration of 25 grams of dihydroxyacetone the increase in blood sugar above the basal value was not greater than that found in normal individuals, and in one there was a slight decrease. With one exception the total sugar excretion for the three hours following its administration was less than the amount excreted during the hour prior to its administration. It would thus appear that the drug has some influence upon the excretion of glucose. In one case the authors found that dihydroxyacetone could replace small amounts of insulin, at any rate temporarily.

627.

#### Bismuth Hydroxide as an Antisyphilitic.

S. LOMHOLT (*Ann. de Derm. et de Syph.*, April, 1925, p. 260) condemns all oily suspensions of bismuth on the ground that they are very slowly and irregularly absorbed. If any oily preparation be used it should be the potassium-sodium tartro-bismuthate, on account of its solubility in the fluids of the body. On the other hand, aqueous solutions and suspensions are absorbed rapidly and regularly, but the aqueous solution of the above-mentioned salt causes considerable pain when injected in sufficient quantity, and it is so rapidly eliminated that its routine employment is impracticable. The bismuth content of iodo-quinio-bismuth is low and inconstant. Lomholt recommends bismuth hydroxide, which is prepared by dissolving bismuth subnitrate in dilute nitric acid and neutralizing it with excess of ammonia. The white precipitate of bismuth hydroxide is ready for use after washing, but it is very unstable when suspended in distilled water; this, however, is corrected by adding 10 to 25 per cent. glycerin to the suspension, which is quite homogeneous and so slightly hypertonic that it is almost painless on injection. All bismuth suspensions must be shaken immediately before injection. Lomholt investigated the ratio of absorption and elimination, using a 10 per cent. suspension of bismuth hydroxide in a 25 per cent. glycerin and distilled water mixture. During the first fourteen days the quantity of bismuth eliminated in the urine was slightly more than 40 per cent. of the total quantity injected; he presumed that the quantity eliminated in the faeces raised the total amount eliminated to approximately two-thirds of the bismuth injected. Lomholt concludes therefore that this is a particularly safe, inexpensive, and easily prepared preparation of bismuth, there being no danger of poisoning from accumulation of bismuth in the system, nor of failure of the treatment through too rapid elimination. The formula recommended is: freshly prepared bismuth hydroxide emulsion 10 c.c.m., glycerin 10 c.c.m., distilled water 50 c.c.m. Lomholt usually gives one weekly injection containing from 10 to 30 cg. of bismuth according to the patient's weight; a faint "bismuth line" appears at the edge of the gums, sometimes after three or four injections, usually after seven or eight. He gives a series of eight to ten injections and has seen no serious toxic symptoms.

628.

#### Iodine in Exophthalmic Goitre.

A. S. JACKSON (*Annals of Surgery*, April, 1925, p. 739) states that following Plummer, he began, in 1922, to treat exophthalmic goitre cases with Lugol's solution (5 per cent. iodine and 10 per cent. potassium iodide). The first 20 cases showed remarkable clinical improvement, gastro-intestinal crises abating within forty-eight hours, and the more toxic cases especially being benefited. Later he increased the amount of iodine, and had no case of hyperthyroidism; this series included 50 cases, and in the last 25 of these no preliminary

ligature was necessary in the thyroidectomy. The author emphasizes the necessity for careful diagnosis in order to avoid iodine hyperthyroidism. He observed that in cases treated with iodine the pulse rate and basal metabolism rate fell together. He recommends that after careful physical examination patients who have not lost much weight and have a basal metabolism rate not exceeding + 75 per cent. should be given 10 drops of Lugol's solution before meals for three days, and also 30 drops of tincture of digitalis, 1/4 grains of luminol is given each afternoon. If improvement results after three days the patient is admitted to hospital and 10 drops of Lugol's solution is given every hour for five hours. The following morning thyroidectomy is performed under morphine-scopolamine-novocain anaesthesia. Immediately after the operation 10 drops of Lugol's solution is given by the rectum, and two hours later another dose is given by the mouth, 50 drops being usually given during the first twenty-four hours after the operation, 30 drops on the second day, and so on day by day, depending upon the rate of recovery. The average stay in hospital was five days. Patients with loss of weight amounting to 40 or 50 lb. who have a basal metabolism rate of over + 75 per cent., or who show any signs of an approaching crisis, require longer and more careful preparation. Jackson sums up the value of iodine administration in thyroid surgery as follows: (1) Patients are not brought in a precarious state to the operating theatre; (2) nervousness is diminished very greatly; (3) a multiple stage thyroidectomy is unnecessary; (4) a preliminary ligature is unnecessary; (5) haemorrhage is less because there is no previous ligature and therefore no collateral congestion. The morbid histology of the thyroid is stated by Jackson to undergo changes during iodine administration. A transitory stage occurs in which colloid replaces areas of hyperplasia and the gland begins to assume a more normal appearance, but unfortunately this return to normal is never complete.

## Laryngology and Otology.

### 629. Echinococcal Cyst of the Frontal Sinus.

CITELLI (*Rev. de Laryngol., d'Otol. et de Rhinol.*, April 15th, 1925, p. 236) remarks that, although hydatid cysts are much more common in the liver than in any other organ, they have been known to occur in nearly all parts of the body. So far, however, there have been no well authenticated cases recorded as occurring in the nose or accessory sinuses. One possible case of hydatid cyst of the frontal sinus was removed by Langenbeck in 1818, and was reported by Davaine (*Traité des entozoaires*, 1877, p. 584). Citelli now reports a case which came under his observation in 1915. From a boy aged 4 a hydatid cyst of the liver without fluid was removed. Since the age of 3 the patient had had a slight deviation of the right eye, caused by a tumour in the superior internal angle of the orbit. This growth had increased progressively and slowly until 1915, when the boy was 11 years of age. It was then a well marked, hard, smooth, rounded mass in the superior internal angle of the right orbit, and involved the inner part of the roof. There was also some slight ophthalmos and a deviation of the globe outwards and downwards; the nasal fossa was normal. Radiography showed complete opacity of the right frontal sinus, with the cranial wall of the sinus pushed inwards towards the cranium. There was scarcely any spontaneous pain, but a slight sensibility to touch. Ogston-Luc's operation was performed, and Citelli found the cavity full of a rounded mass, externally white and fibrous, internally yellowish and granulated, which showed all the typical appearances of an echinococcal cyst. After removal the patient made an uneventful recovery in ten days.

### 630. Diagnosis of Antral Disease.

W. L. BURNAP (*Minnesota Medicine*, April, 1925, p. 203) remarks that in the search for infective foci antral empyema is frequently overlooked owing largely to the erroneous belief that certain symptoms, such as nasal obstruction, pain, and unilateral nasal discharge, must be present. Experience shows that subjective symptoms are often misleading, as a large number of patients with arthritis and similar infections have no head symptoms. J. P. Tamm, in 100 autopsies, found 37 cases of antral disease, including 12 cases of chronic inflammation or empyema; only one case was diagnosed during life. The ostium of the antrum is situated high up in the middle meatus; drainage depends, therefore, upon the dilated epithelial lining. These conditions increase the number of infections and retard recovery. The antrum may be infected without dental disease, but the tooth should be considered first in all cases. A case of chronic nasal catarrh was cured by extraction of a dead premolar and evacuation of a secondary empyema. The author states that interpretation of dental films regarding relation of

the antrum to the tooth roots demands much skill and experience. If the dental apex is in contact with the antral wall there will be no area of bony softening and absorption; consequently many diseased teeth escape detection. Chronic antral infections may be discovered accidentally during a secondary infection. When examining the nasal fossa it is most important to spray or swab the mucous membrane with an adrenaline-cocaine solution; this contracts and blanches the nasal mucosa. Careful search for purulent discharge should be made, and if none be seen a suction bulb should be used. If pus appears in the middle fossa its origin must be investigated. Transillumination, skiagraphy, and puncture are the three chief methods of differential diagnosis; the first should never be omitted as the pus may be too thick to pass the antral ostium. Pain, often unilateral and severe, occurs as a rule in acute cases, but may be absent in the chronic; it usually indicates retention arising from partial or complete ostial occlusion, due to a thickened mucosa, polyp, or inspissated pus. The pain is felt usually in the cheek or around the eye, but may be referred to the ear and mastoid. Transillumination should always be employed, but requires careful interpretation; where it indicates a difference in antral density skiagrams should be taken. These will also assist greatly in determining the presence of any frontal, ethmoidal, or sphenoidal involvement: trocar puncture through the middle fossa usually gives incontrovertible evidence. Burnap concludes that acute and chronic maxillary antral infections are very common, but very few cases are diagnosed early, the majority persisting unrecognized for many years. Good treatment includes drainage and ventilation, under which the mucosa recovers rapidly in acute cases and ultimately in most chronic cases. When permanent intranasal drainage has been established few subsequent treatments are required. Radical and mutilating operations are never necessary in nontoxic infections and rarely in chronic infections.

## Obstetrics and Gynaecology.

### 631. Sympathectomy in Gynaecology.

R. LERICHE (*Presse Méd.*, April 11th, 1925, p. 465) recapitulates his experience of periarterial sympathectomy on the pelvic blood vessels, which operation he has performed twelve times since 1917. Division of the sympathetic along the internal iliac was sometimes accompanied by section of that along the ovarian or common iliac artery. One patient with metrorrhagia of unknown origin experienced temporary benefit; severe dysmenorrhoea was relieved in one case for two and a half years, and in another case for six months at least, the two patients concerned having a small mobile uterus and polycystic ovarian transformation. One patient suffering from kraurosis vulvae obtained complete relief lasting three years, and another was benefited. A patient who suffered intense pelvic pain after radium treatment for cervical carcinoma, but who showed no trace of recurrence, appeared cured after periarterial sympathectomy of both internal iliacs. Operative difficulties were encountered in one case only. Leriche reserves his opinion concerning the utility or expediency of adding to the operation a division of the presacral sympathetic, as suggested by Cotte. He concludes that periarterial sympathectomy is probably a valuable procedure in many cases which resist other treatments and which have too often been treated by useless or harmful ovarian excisions.

### 632. Tuberculosis of the Body of the Uterus.

C. DANIEL (*Gynéc. et Obstét.*, 1925, xi, 3, p. 162) states that modern investigations have shown that tuberculosis of the uterine body is much more common than was formerly supposed. Although usually it is secondary to other lesions in the lungs, lymphatic glands, kidneys, bones, Pott's abscess, cervix, or elsewhere, yet it is certain that in a fair number of cases the affection of the corpus uteri is primary. Simmonds found among 80 autopsy cases of genital tuberculosis in the female that 11 per cent. were of the uterus only, 23 per cent. of the tubes only, and 65 per cent. of both uterus and tubes. Although tuberculosis of the uterine body is found in childhood and after the menopause, the majority of published observations relate to women in full genital activity; the puerperal state seems to favour inoculation of the uterus with Koch's bacillus. As a rule the endometrium is affected first, with secondary extension to the myometrium; miliary, caseous, and hypertrophic forms have been described. An example of the last named is recorded by Daniel. The patient, a 7-parous woman aged 50, suffered from pain, fetid discharge, and irregular haemorrhage about two years after the menopause, and had within the uterus, in addition to

endometrial vegetations, a sessile submucous tumour the size of a small apple. Among the complicating conditions are: pyometra, which does not invariably occur in aged subjects; atresia of the whole uterine cavity; spontaneous rupture of the uterus; and carcinoma of the body of the uterus. Diagnosis is difficult, although in a small proportion of cases tuberculous material may be recognized in the fragments taken for biopsy; it is usually made after microscopical examination of the excised uterus. Danlot regards radical surgical intervention, if possible by the vaginal route, as the only rational mode of treatment. He notes, however, that Italian writers have strongly recommended hysterectomy and other conservative treatments, and that Cuzzi claims to have had, in a woman who had been fourteen times cured, a complete cure after radiotherapy followed by pregnancy and labour.

### 633. Prophylaxis in Puerperal Fever.

H. BIERMER (*Zentralbl. f. Gynäk.*, March 28th, 1925, p. 674) reports the result of administration simultaneously of anti-streptococcal vaccine and antistreptococcal serum to 94 patients in whom infection appeared likely to occur after abortion or delivery at term. The effects of such an attempt to confer active and passive immunity have been found by Leuros and others to be favourable. Biermer, however, states that 24 per cent. of his cases afterwards became febrile, compared with 8 per cent. in a control series in whom no attempt at immunization was carried out, and relatively three as many obstetric operations were followed by infection in those who had received the serum and vaccine. He concludes that it is fallacious to regard the simultaneous administration of a protective serum as annulling the danger of giving a vaccine during the "negative phase" of an existing slight infection. Clinically the treatment seemed sometimes harmful, especially in patients who had lost a good deal of blood.

### 634. Congenital Elongation of the Cervix.

ACCORDING TO P. SÉJOURNET (*Bull. Soc. de Gynéc. et d'Obstét. de Paris*, 1925, 4, p. 276) congenital lengthening of the cervix is occasionally met with in the newborn; in the absence of vaginal or uterine prolapse the cervix protrudes from the vulva, and other malformations, such as club-foot and spina bifida, are often present. In the adult, congenital cervical lengthening presents itself in partial and complete forms; in the former the anterior lip is usually affected and may attain the length of 10 cm. The complete form is not usually detected until after a full violent muscular effort, or coitus. Séjournet mentions the case of a patient who suffered from dysmenorrhoea and sterility which were finally relieved by cervical amputation, the elongated cervix being folded upwards on itself in the posterior fornix. Exteriorization of an elongated cervix, unlike the cervical hypertrophy associated with precociousity, is frequently met with in young virgins and in young nulliparae with intact perineum. It may nevertheless cause symptoms only at a later age. Two cases are described of this condition occurring in unmarried women. In the first, aged 40, the cervix after four years' diurnal descent became permanently exteriorized. The second patient, aged 47, who when sitting down felt a "falling," worse at the menstrual periods, had a cervix 7 cm. long which increased markedly in size at the menses. Séjournet adds that completely elongated cervixes measure as a rule from 5 to 8 cm., although Tédénat recorded one of 15 cm. Treatment consists in high amputation at the cervico-vaginal insertion.

## Pathology.

### 635. Vitamins and Bacterial Growth.

P. GOY (*Ann. de l'Inst. Pasteur*, February, 1925, p. 183) discusses the effect of vitamins on the growth of yeasts, moulds, and certain bacteria. Working with *Aspergillus niger*, he found that the addition to Rabin's solution of a heated filtrate of a culture of *Mucor mucedo* in the proportion of 3 per cent. increased the growth to such an extent that the yield was as great in 60 hours in this medium as it was in 130 hours in the control medium. Similarly he was able to show the beneficial effect on the growth of *Saccharomyces cerevisiae* of a heated culture of *Amylomucor*  $\beta$ . The substance present in this mucor which is responsible for increasing the growth of other organisms appears to be different from vitamin B. Thus it can be extracted from polished rice and from meat, neither of which contains the B factor; moreover, the extract of *Amylomucor*  $\beta$  itself has been shown by experiments on the higher animals to be free from vitamin B. Other differences were established, such as

the heat stability of the mucor extract (it withstood autoclaving at 130° C. for one and a half hours, even when the solution was acid or alkaline), its complete solubility in ether, and its filtration through kieselguhr without loss of potency. The addition of the filtrate of *Amylomucor*  $\beta$  to broth, and to certain other media, increased the growth of several microorganisms, such as the streptococcus, the *D. diphtheriae*, the tubercle bacilli, and several of the pathogenic anaerobes. The chief effect was not, apparently, increase of the total yield of the culture, but increased rapidity of the growth. Goy suggests, therefore, that the addition of this substance might be useful when an early growth is desired.

### 636. Antidiphtheritic Vaccination.

VARIOUS methods have been devised for producing an active immunity to diphtheria. Von Behring introduced the toxin-antitoxin mixture; Glenny and Sjödmersen recommend a formalized toxin—or anatoxin—which has the advantage of being free from some of the objectionable features of the first. A. SORDELI and R. SERA (*C. R. Soc. de Biologie*, March 20th, 1925, p. 824) now suggest another method, depending on the precipitation which occurs when antitoxin is incubated with toxin. Using Ramon's technique, the amount of antiserum is determined which will neutralize a given quantity of toxin in one hour and in twenty-four hours. In one experiment these amounts came to 14 and 7 c.cm. respectively. A mixture is now made up containing 9 c.cm. of antiserum and 100 c.cm. of toxin. Flocculation occurs after an hour at 38° C.; the mixture is left for a further twenty-four hours in the ice-chest at a temperature of 3° C. and is then centrifuged. The immunizing powers of the supernatant fluid and of the precipitate are then tested on guinea-pigs. It is found that both have much the same antigenic power, though, volume for volume, the precipitate is about 250 times more active. This concentration of the immunizing bodies in so small a quantity of precipitate is the essential part of the method. Vaccination can be carried out either by intradermal injection or by inoculation of the scarified skin, as in ordinary vaccination against small-pox. Testing the value of the two methods on guinea-pigs and rabbits, the authors found that the intradermal injection method gave rise to a higher degree of immunity than the other method. They advocate the employment of this concentrated overneutralized toxin for human vaccination.

### 637. The Streptococcal Toxin and the Dick Reaction.

J. PARAF (*Bull. et Mém. Soc. Méd. Hôp. de Paris*, March 19th, 1925, p. 395), applying the Dick test to 78 adults (doctors, nurses, students, and patients with chronic tuberculous or nervous diseases), found that 26 were positive and 52 negative. Of 5 who had had scarlet fever, 4 gave a negative and 1 a positive reaction. Of the remaining 48 with negative reactions 9 were subject to recurrent sore throat and 1 had had facial erysipelas seven years previously. The proportion of positive reactions (33 per cent.) was lower than that found by Dick and Zingher (41 per cent.). Among 46 children below the age of 14, 20 gave a positive and 26 a negative reaction; 16 of the latter were convalescent from scarlet fever, and 2 had had the disease two or three times. Among 12 children, aged from 1 to 6 months, 4 were positive and 8 negative. Among 8 of these 12 children the test was performed on both mother and child. In 5 infants, aged from 1 to 6 months, the reaction was the same as in the mother—namely, negative in 4 and positive in 1. In 3 infants, aged from 6 to 18 months, the reaction was the same as in the mother, but in an infant of 13 months the reaction was positive while its mother's was negative. Paraf points out that there is therefore, as in diphtheria, sometimes a transmissibility of streptococcal immunity from mother to child. This immunity becomes attenuated and finally disappears in the course of the second year, when the reaction in the child is often different from that in the mother. The Dick reaction therefore runs absolutely parallel with the Schick reaction under similar conditions. In a certain number of cases Paraf made use of a streptococcus isolated from diseases other than scarlet fever—such as acute malignant endocarditis, erysipelas neonatorum, and fatal puerperal fever—for the preparation of the toxin, and gave intradermal injections of these toxins simultaneously with the scarlatinal toxin, the results being always identical. He also performed the test in a few cases of streptococcal infection. The result was positive in a case of subacute endocarditis and one of recurrent erysipelas, but negative in a case of puerperal phlebitis and one of infection following abortion. These results seem to indicate a paraspecific immunity resembling the phenomenon of paradoxical agglutination observed in typhus.

## British Medical Association.

### DRAFT MEMORANDUM OF EVIDENCE PROPOSED TO BE PLACED BEFORE THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

*(Here will appear an introductory section dealing with the authority which the Association has for dealing with this question and the way in which it has secured the approval of the profession for the views submitted.)*

The following sections of this Memorandum are not self-contained, and must be read in connection with each other.

1. The subject of this Memorandum is the organisation of a national scheme of health insurance so far as medical services are concerned and the relationship of such a scheme to other services concerned with public health.

#### GENERAL.

2. At the outset it is desired to emphasize two general considerations. The first is that the organisation of a national health insurance scheme is not necessarily, or even probably, the best means of utilising limited resources for the promotion of national health. It is more than likely that there are a number of other directions in which, severally or collectively, a corresponding expenditure would produce an even more satisfactory return. Such are (1) proper housing, (2) town-planning with the proper provision of open spaces and recreation facilities, (3) smoke abatement, (4) a pure milk supply, (5) public-house reform and the regulation of the sale of alcoholic beverages, (6) the destruction of vermin, (7) education, (8) the aiding of medical research.

3. If, however, resources are sufficient, or if for other reasons it is deemed desirable to organise a national health insurance scheme, a second general consideration becomes of paramount importance, viz., that regard should be had primarily and constantly to the maintenance of health and the prevention of disease and not merely to provision for the alleviation or cure of morbid conditions when once they have arisen. To this end it is essential not only that the attention of all practitioners should be directed continually to the preventive aspects of their work, but that the existing machinery and medical officers of the public health service should be brought into close and organic connection with the insurance scheme.

4. A national health insurance system is understood to be one through which, in return for premiums paid or contributions made, participants are entitled to medical attendance and

treatment, together with certain services ancillary thereto, and also to cash payments under certain conditions during ill-health or disablement. The medical profession, as such, is concerned only with the former class of these benefits, and with the giving of such certificates and reports as may be required in connection with the latter class.

5. The system established under the National Health Insurance Acts is on these lines. The medical profession has now had experience of it since January, 1913. At the beginning the success of the system was jeopardised by the facts that a large proportion of professional opinion was antagonistic to the system or to some of its important details, that sections of the insured population shared this antagonism, and that a lack of experience, combined with the overwhelming amount of work involved, led on the one hand to unsatisfactory practice arrangements, and on the other to very imperfect administrative machinery and methods. A little later the immense disturbance of the war and of demobilisation prevented acquired experience from having its full practical effect, and it is during the last three years only that the system can be said to have been working in a really smooth and normal fashion. Indeed, some essential improvements came into force only at the beginning of 1924. Nevertheless, in the year 1922 both the Representative Body of the Association and the Conference of Representatives of Local Medical and Panel Committees declared "that the measure of success which has attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the profession in uniting to ensure the continuance and improvement of an insurance system."

6. A comparison of the conditions of practice among the classes to which insured persons belong, before and since 1913, leaves no doubt in the mind of the profession (a) that large numbers, indeed whole classes, of persons are now receiving a real medical attention which they formerly did not receive at all; (b) that the number of practitioners in proportion to the population in densely populated areas has increased; (c) that the amount and character of the medical attention given is superior to that formerly given even in the best of the old clubs, and immensely superior to that given in the great majority of the clubs which were far from the best; (d) that illness is now coming under skilled observation and treatment

at an earlier stage than was formerly the case; (e) that, speaking generally, the work of practitioners has been given a bias towards prevention which was formerly not so marked; (f) that clinical records have been or are being provided which may be made of great service in relation to medical research and public health; (g) that co-operation among practitioners is being encouraged to an increasing degree; and (h) that there is now a more marked recognition than formerly of the collective responsibility of the profession to the community in respect of all health matters. All these are immense gains and, though it is possible that some of them may not be wholly due to the establishment of the National Health Insurance scheme, they have certainly been hastened and intensified by that system.

7. On the other hand it has to be said that this very success had led, at certain seasons, and in times of widespread epidemic disease, to a strain upon its powers and resources which the profession has scarcely been able to bear; and the new conditions have resulted in a volume of regulations which must be observed, rules which must be obeyed, forms which must be filled up, and quasi-judicial machinery which it is desirable to avoid, to an extent which is regarded by insurance practitioners as oppressive, or even menacing, and which actually by itself deters some other practitioners from taking part in the service at all. The doctor is still an individual dealing with an individual patient and having his prime duty in this relationship; and in so far as his mind is seriously diverted from this by concern for other duties and relationships, and by fear of transgressing unwittingly rules and regulations made for other purposes, this is detrimental to his work and to the interests of those whom he is primarily serving. It is, of course, true that all citizens live and work under the restraining influence of law and social custom, and that members of the medical profession have also in mind the disciplinary powers of the General Medical Council and the ethical and other traditions of their profession, but in the world, even in the medical world, these are not so onerous, so omnipresent, so imminent, as to be a constant source of worry or distraction. Experience of the National Health Insurance system as at present established has led the profession to realise very vividly that its work may be made not more efficient but less efficient by a multiplicity of departmental requirements. Its aim is so to improve the system as to enable the profession to supply what the public needs under conditions which will make its services most easily and suitably available to the community.

8. It is the belief of the Association that in any national health insurance scheme certain broad principles with regard to medical benefits must be regarded as fundamental. These are:—

(a) The medical provision should be available for those persons, and only for those persons, who would be unable to obtain it without the help of the insurance scheme;

(b) The medical provision made for such persons should be, as far as possible, complete;

(c) The conditions under which the medical attention is given to the individual should approximate as nearly as possible to those of private practice;

(d) Medical representatives should be closely associated with the administration of the scheme, and as far as questions of purely professional conduct and treatment are concerned, judgment should be in the hands of purely professional bodies;

(e) Remuneration should be on such a basis as (i.) would produce an income not less than that which corresponding responsibility and work should produce in comparable private practice, regard being had to all relevant considerations, and (ii.) would not prejudice the continuous supply of the best type of practitioner.

9. If these conditions are not secured there will be grave danger (1) that the volume of work imposed upon the medical profession will be much greater than it can properly perform, at any rate for some time to come; (2) that much of the advantage of present professional feeling and tradition will be lost and the present relationship of doctor and patient be changed for the worse, to the prejudice of the patient; (3) that work under the insurance scheme will be regarded as of only secondary importance when compared with other branches of medical practice.

#### SECTION A. PERSONS TO BE PROVIDED FOR.

10. The first of the above principles raises at once the question as to the extent of the national health insurance service as regards the persons for whom provision should be made. Within the present scheme are included all persons under a contract of service, namely, (a) all manual workers, without limit of £230 a year. Any such employed person who has a private

income or pension of not less than 10s. per week, or is ordinarily and mainly dependent for his livelihood on some other person, may claim exemption and is then required to make his own arrangements for medical attendance if his total income is above £160 a year (i.e., if his earned income is more than £134 a year or even less than this). Such persons are exempt from insurance in general but entitled to Medical Benefit. Further, certain whole classes of persons are excluded because, though under a contract of service, they serve under conditions which provide, by means of a superannuation scheme or otherwise, benefit considered to be at least equivalent to those of the national insurance scheme. On the other hand, certain persons who have been compulsorily insured for at least two years may continue their insurance voluntarily, even though they have ceased to be under a contract of service. These, however, are a relatively small number.

11. Questions which arise are (1) whether it is necessary to include within a national health insurance scheme all such persons as are at present included; (2) whether it is not at least equally necessary, from a national point of view, to include those economically dependent upon such persons, and also other workers who, though not under a contract of service, are in a like economic position; (3) whether it is desirable to include within the same system of medical benefit those who are actually destitute, in this case of course with appropriate modifications as to contributions.

12. It is impossible to resist the conclusion that provision for those referred to in the second question is necessary, and that the provision that must be made for those referred to in the third question might well be made by the same system. It is recognised that neither of these problems is a simple one. From the national health point of view the Association holds that the dependants of the lower paid insured person should have provided for them through some insurance system medical advice and treatment, but is opposed to the inclusion of the dependants of the whole of the present insured persons.

13. The problem of the inclusion of the dependants of even the lower-paid insured workers in any insurance scheme raises questions of paramount importance. However obviously desirable this may be as a matter of national health, it clearly involves some formidable difficulties. These are mainly (a) finance, (b) amount of additional work imposed on the medical profession, (c) consequential alterations in the conditions of practice in many areas.

14. The additional financial burden will be dependent on two factors: (a) the number of new participants, (b) the proportionate cost per head of each of these to that of persons previously insured. There does not appear to be any exact estimate of the number of dependants, but assuming for the moment that the number of existing insured persons (say 15,500,000) remains the same, the number of their dependants plus others in a like economic position is possibly something like one and a half times as great—that is to say the present insured persons plus their dependants would probably amount to 38,750,000 in all. There is no reason to suppose that such new entrants would be less costly than their predecessors. The total amount of work thrown on the medical profession is another factor of great importance, and it must be remembered that the demands under an insurance scheme would necessarily and properly be considerably heavier than those at present made by the same persons. This fact emerged during the early years of the operation of the National Insurance Scheme.

15. The profession would no doubt in the course of time adjust itself in numbers and in other ways to the new conditions, but for a considerable time to come, and perhaps permanently, in order to cope properly with the new work, and to make it tolerable by the profession—especially in those areas in which, owing to the character of the population, there would be left no scope at all for other practice—some arrangements tending to lighten the work would have to be made. The Association is of opinion that essential conditions accompanying any extension of a national health insurance scheme to include dependants and others of a like economic status should be (a) the establishment or continuance in all populous areas of infant welfare centres for the instruction of mothers and for the routine examination of infants and young children as to weight, etc., the practitioner having reasonable access to the records of all cases under his care; (b) a sufficiently adequate service of nurses available for home nursing; (c) the reduction to a minimum of all records and reports required from practitioners with regard to the new entrants and a lightening of those required with regard to existing insured persons; (d) a revision of the matters which may be made the subject of complaint and of the methods of dealing with them on the lines of the suggestions made in a subsequent section of this memorandum.

16. With a view to reducing further some of these difficulties and liabilities, and bringing the whole problem within more measurable compass, it is suggested—

(a) That the classes of persons exempt from the scheme by reason of their contract of service including provisions giving benefits equal to those of the national scheme, should be extended to include others (e.g., bank and insurance clerks) not at present excluded;

(b) That persons with an unearned income of an amount per week not less than that prescribed for sickness benefit should be excluded;

(c) That any income limit (whether £250 a year or a lower amount) should be applied alike to the non-manual worker, the manual worker, and the voluntarily insured person;

(d) That a lower income limit than that which is applied generally to insured persons should be necessary with regard to the inclusion of dependants.

17. It is not suggested that these income limits are exact criteria of economic need, but in view of the considerable increase in the total of medical advice and treatment which would be entailed by the inclusion of dependants and others in like economic position, it seems necessary, at any rate for a time, to draw the line of inclusion in the scheme as low as is reasonably possible, rather than as high as in other circumstances might be found desirable. The question of whether a contribution from the employer should be required for every one of his employees regardless of all, or any of the suggested exemptions, is not a medical question and is not prejudiced by the above suggestions.

18. From the medical side only, the problem of the provision of advice and treatment for the poor person not under any contract of service, or for the necessitous person, is not specially difficult. The difficulties here are the details of finance and administration. If these can be overcome the profession is prepared to undertake the work in general accordance with the National Health Insurance Scheme here outlined.

#### SECTION B. EXTENT OF PROVISION TO BE MADE.

19. The second of the main points is that the medical provision made for all persons included in the scheme should be, as far as possible, complete. Under the present scheme the medical advice and treatment provided is, broadly, such as can reasonably be expected from general practitioners as a class. Other services publicly provided under the auspices of local authorities are also available—certain pathological facilities, treatment for tuberculosis and venereal disease, and for certain infective fevers, the treatment of certain conditions of children of school age and provision in connection with maternity and infant welfare. Moreover, some Approved Societies make contributions to some of their members toward the cost of a few other treatments, e.g., dental, ophthalmic, or institutional. These benefits are, however, available for only a small proportion of insured persons, although all pay the same premiums. A further small provision for possible consultative advice by or through the regional medical officers, is, so far, scarcely at all developed.

20. It is desired to make all such services and benefits an integral part of the insurance scheme or to bring them into proper relationship thereto, so that they may be available for all persons included; and to extend the provision so as to include complete consultant and specialist advice and treatment, full laboratory facilities for clinical purposes, residential institutional treatment so far as possible with limited accommodation, dental advice and treatment, such ancillary help as can be given by nurses and masseurs, and an ambulance service—in addition to the general practitioner advice and treatment and the provision of necessary drugs and appliances which is at present the main provision made. The Association is of opinion that all these benefits should be equally available to all insured persons alike regardless of their membership of any particular society.

21. It seems necessary here to emphasise that when "general practitioner advice and treatment" is spoken of, the phrase does not indicate anything of an inferior character. In their own way and for their own purposes, such services "as can reasonably be expected from general practitioners as a class" are fully as important, as scientific, as highly skilled, as those which are provided by other practitioners in more special and restricted lines of practice. Practitioners, whatever their sphere of practice, may be relied upon to devote to their work all the knowledge, care and skill which they have; the distinction is mainly one of range. Experience and skill in certain directions can only be acquired by those (some general practitioners included) who are able to direct special attention to a particular branch of practice or class of case, or to the performance of certain surgical operations or manipulations.

It is desirable to secure all these different kinds of skill for the participants in an insurance scheme, without implying that one kind is superior in itself to another.

22. It is obvious, as is the case at present in connection with the provision of drugs and appliances, that persons who under the scheme would be eligible for all the additional services could not be put into a position to claim them whenever they wished. Otherwise demands might be made which would be disadvantageous medically and ruinous financially. With slight modification in one or two instances these services should be available only on the recommendation of the general practitioner responsible for the patient. This rule, however, might require safeguarding in two directions. On the one hand it is conceivable that a practitioner might make unreasonable or excessive use of these facilities, and accordingly practitioners might be (a) required to notify the administrative authority on recommending a patient for these extra services, and (b) liable to explain to a professional committee the reason for any apparently excessive use. On the other hand there might be cases, as in private practice, in which there might be a difference of opinion between practitioner and patient as to the need for the extra service, or cases in which a society or other body responsible for cash payments during sickness might make a request for further special advice, and accordingly provision might be made for an official referee to decide the matter in such cases where necessary.

23. The cases calling for a modification of the general rule that services should be available only on the recommendation of the general practitioner responsible are (a) the prescribing of any necessary drugs or appliances, or the using of other extra services by the consultant or specialist to whom the patient has been referred not for consultation only but for the carrying out of some special investigation or treatment; and (b) the direct application by the patient to a dentist for dental treatment. In the latter case some safeguards would be required for dental services of specified kinds or for any procedure estimated to involve expenditure beyond a stated amount.

24. The medical personnel of the consultant or specialist service should consist of all registered medical practitioners who expressed their willingness to accept service within each area and who satisfied certain criteria as to status. These criteria should be those at present laid down in the Medical Benefit Regulations and elsewhere for a similar purpose. These are:—

(a) That he has held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service rendered, and has had actual recent practice in performing the service rendered or services of a similar character; or

(b) That he has had special academic or post-graduate study of a subject which comprises the service rendered, and has had actual recent practice as aforesaid; or

(c) That he is generally recognised by other practitioners in the area as having special proficiency and experience in a subject which comprises the service rendered.

The decision as to whether any individual practitioner desiring to serve in a consulting or specialist capacity does in fact satisfy these criteria should be in the hands of a local professional committee. Any practitioner excluded by the decision of such a committee should have the right of appeal to a small professional committee representing a wider geographical area. From a list of consultants and specialists so compiled a practitioner, in agreement with his patient, might choose any individual considered most suitable for the particular case.

25. In normal circumstances, or whenever possible, such consultations would take place or such specialist services would be given, either at the consultant's rooms, or at the practitioner's house or surgery, or at the patient's house. The conditions in some localities, however, might make desirable the establishment of special premises for this purpose, and such premises might in some cases even be the out-patient department of a hospital. Wherever such consultative or specialist clinics were established attendance would have to be given by the medical officers at fixed times, the clinic should be available for the purposes of medical education, particularly post-graduate, and general practitioners not on the specialist list should be eligible for service as clinical assistants.

26. Among the detailed arrangements that must be made for the conduct of such a service is the important one for exchange of opinion and co-operation in treatment between the general practitioner responsible for the case and the consultant or specialist to whom the patient has been referred for advice or treatment. It is desirable that a system should

be adopted whereby the practitioner referring a case would furnish the consultant by some method with information of the previous history and points on which advice is specially desired, and the consultant would furnish the practitioner with information as to the results of his examination and any treatment given or future treatment advised. Provision might be made for insisting upon actual personal consultation between practitioner and consultant where either of them considered this necessary. The primary responsibility of the general practitioner in charge should be preserved in all cases.

27. The relation of certain existing clinics or treatment centres, provided by local authorities under statutory powers, to the suggested arrangements must be considered. Obviously in so far as persons provided for by these clinics come under a health insurance scheme, and so far as the treatment provided thereat is either general practitioner treatment or such as can normally be given by a consultant or specialist elsewhere, they would no longer be required. If they remained—as in many cases no doubt they would—their functions would be somewhat as follows:—(a) they would be centres for education in health matters; (b) they would be places at which practitioners might make appointments with their patients when necessary for special purposes; (c) they would be specialist clinics for persons under the insurance scheme where consultations elsewhere were not possible; (d) they would be available for public provision for such persons as did not come under the insurance scheme when such provision was still held to be necessary for certain purposes.

28. It is possible that for a limited period of time it would still be necessary to continue the appointment of whole-time officers dealing with tuberculosis and with venereal diseases.

29. The relationship of maternity work to the health insurance scheme requires special mention. It is contemplated that complete provision should be made for this as part of the medical service. Provision should be made, in addition to a cash payment, whereby attendance at confinement and during the puerperal period together with special examination and supervision during pregnancy would be brought within the scope of the scheme. Certain conditions are, however, essential if this is to be done: (1) there must be everywhere an efficient service of registered midwives, (2) there should be provision for institutional treatment for serious cases of ante-natal complications, for cases requiring major obstetrical operations, for cases where isolation and treatment of septic infection is specially indicated, and for cases where the home conditions are very unsuitable or dangerous for confinements; (3) any practitioner should be at liberty to decline to undertake this work; (4) practitioners should be at liberty to place their names upon the list for maternity purposes only. Provision for a woman within the insurance scheme would thus be for: (a) medical examination (not compulsory), and supervision during pregnancy; (b) attendance by a registered midwife during normal labour and during the puerperal period (the ideal being that both a midwife and a doctor should be provided, but where the scheme cannot provide for both in respect to normal labour the interests of the patient would best be served by the provision of a midwife; (c) attendance by a practitioner during labour and the puerperal period when his attendance is requested by the midwife under defined conditions, or when, as a result of his examination during pregnancy he has declared his personal attendance to be necessary. Professional services under these headings would be remunerated, as in the case of the other extra services, by a special scale of fees, as indicated in a later section. The procedure would be for the insured woman, at an early stage of pregnancy, to choose her doctor; for the doctor so chosen to make, with her consent, a suitable examination during pregnancy; for the midwife to be notified as to the doctor to be called in, and as to the conditions under which she must ask for his services. The consultant and specialist service would be available also in this connection.

30. The provision for a clinical laboratory service stands on a somewhat different footing. There are advantages in such a service being associated with research work; and suitable laboratories are as a rule connected with universities or hospitals, sometimes the larger voluntary hospitals, sometimes hospitals for infectious disease established by local authorities. When, however, routine investigations are undertaken by a university laboratory, such routine work should not be allowed to interfere unduly with teaching and research which are the proper work of a University Department. It is desirable that the necessary laboratory work should be divided between a relatively small number of large central laboratories and a larger number of small laboratories. At the former, investigations requiring special facilities or appar-

atus or those which can be carried out with greater accuracy, uniformity and economy when large numbers of specimens are dealt with would be made. At the latter, tests not involving the use of elaborate or exceptional apparatus would be carried out. Highly trained pathologists would be required for most of this work, and in practice it would be impossible and undesirable to restrict their activities to work required by the National Health Insurance scheme alone. Under these circumstances it seems desirable that laboratories should be established and maintained under other auspices, and that a suitable financial contribution should be made to them from the National Health Insurance fund in respect of the work which they do for persons included within the scheme. Some approved clinical laboratories under private management might be recognised for the same purpose. There are a number of cases, moreover, in which satisfactory results can be expected only if it is possible to provide pathologists to visit patients in their own homes and take the specimens required for examination. It is advisable to arrange for this, as well as for exchange of opinion between clinicians and laboratory workers.

31. For residential institutional treatment arrangements on much the same plan would probably be found most suitable, at any rate for a considerable period of time. There would be available the voluntary hospitals of various types, the hospitals for infectious disease, and the tuberculosis sanatoriums established by local authorities, and the present poor law hospitals. In use none of them could be restricted to persons under the insurance scheme alone, and the total accommodation in them would be insufficient in many areas. The right of insured persons to admission would thus be limited in accordance with arrangements made with the authorities governing particular hospitals or institutions. A copy of the hospital policy of the British Medical Association will be attached hereto, with those provisions marked which have special applicability to any such arrangement made on behalf of participants in an insurance scheme. This makes it clear that when use is made of voluntary hospitals or other charitable institutions for the treatment of insured persons, either as in-patients or out-patients, the cost of such treatment should not be a charge on the ordinary funds of the institution but should be defrayed in full out of the Medical Benefit Funds of the Insurance Acts, taking into consideration that the charge should include a percentage for the remuneration of the Visiting Staffs of the hospital in accordance with paragraph 32 of the British Medical Association Hospital Policy. The position of convalescent or rest-homes requires special consideration in this connection.

32. Before leaving this section it may be as well to point out that even within the scope of general practitioner treatment at present the provision for the needs of insured persons is not complete. Although there is complete provision for the supply of any drug or medicine which the practitioner in charge of a case may consider necessary (with due provision against sheer extravagance) there is considerable restriction as to the appliances which may be ordered. No doubt the reason for this is financial, but it would be a great advantage to allow all appliances necessary for the sick person to be supplied. In the case of some such appliances it might be possible to arrange for their loan to the insured person where they are required only temporarily.

33. One other contingent suggestion may perhaps be made. If it should be found desirable to continue to require payments from employers in respect of certain of their employees who were not included in the insurance scheme as a whole (i.e., exempt persons but for whom a card has to be stamped by the employer), it might be found possible and advisable to give such employees the benefit of some or all of these extra services by reason of such contributions.

#### SECTION C. REGULATIONS AND TERMS OF SERVICE.

34. A third main principle is that the conditions under which medical advice and treatment is given, whether by general practitioners or consultants, should approximate as nearly as possible to those of private practice, and should preserve within wide limits professional customs and traditions. These traditions and conditions must, of course, to some extent be modified by the facts that the scheme is based upon an insurance plan, and that under the scheme the practitioner undertakes certain responsibilities not to his patient alone but to the State and to societies or bodies administering cash payments during sickness or disablement, but no unnecessary requirements should be imposed either upon the insured person or the practitioner.

35. An essential point is that, as is the case at present, any registered medical practitioner shall be able to participate in the service as a right if he is willing to accept the

conditions, and until his continuance in the service has been properly adjudged to be detrimental to it. Unless this be so, a large part of their possible field of work would be automatically cut off from practitioners who have complied with those tests which have been recognised by the General Medical Council, in this respect the statutory governing body of the profession, as permitting entry to the profession. It seems to follow as a corollary from this that those conditions laid down for acceptance should be as little complicated and onerous as possible, so that as large a number as possible shall be willing to engage in work under a national health insurance scheme. This would be an advantage to the profession, to insured persons and to the public health alike. It is believed that the suggestions in this and the following section would tend, if adopted, to increase the number of practitioners willing to take part in this work.

36. The main fact of daily professional work is the intimate and confidential relationship which must necessarily arise between patient and doctor and without which, in a large number of instances, results must be far less satisfactory than would otherwise be the case. A very important factor in preserving this relationship is the right of a patient at any moment to seek the services of another practitioner and the right of a practitioner to intimate that he wishes no longer to be responsible for a particular case. All questions of supposed neglect or lack of success or improper behaviour on the part of a doctor, and of unreasonable conduct on the part of a patient may be solved very simply by the exercise of these rights, and there is no reason why, speaking generally, in reference to such matters, specific rules accompanied by penalties should be imposed on insured persons or special provision be made for complaints against practitioners, if a similar freedom of choice can be exercised. This freedom has been secured absolutely for insured persons under the regulations which came into force in 1924, but the corresponding freedom of the practitioner is still unnecessarily restricted. It should be equally absolute except that he should not abandon his responsibility for an actually ill person until other attendance has been secured. In the circumstances indicated it is obvious that the desirable thing to do is not to keep doctor and patient tied together as long as possible but to make other arrangements as rapidly as may be, and to do this with as little unpleasantness or recrimination as possible. There can be no objection, of course, to a statement in general terms as to what constitutes reasonable conduct in certain respects on the part of a patient, or what are in general the duties which the doctor undertakes to perform.

37. The conditions of an insurance scheme also make certain requirements or provisions necessary which are not needed in the conditions of private practice. These, however, though important, should be few. An insured person should be required (1) to seek acceptance by a doctor before occasion for medical treatment arises; (2) to claim treatment as an insured person, by the production of a medical card or otherwise, on at least the first consultation of each series. Failure in either of these respects should render the insured person liable to a penalty or to the payment of a fee, for otherwise an essential principle of insurance is violated or the doctor is placed in a serious difficulty as to his duty. An insurance practitioner should be liable to a penalty for (1) wilfully charging a fee for any service which he had undertaken to render as part of the insurance service; (2) such general conduct as is held to be detrimental to the interests of the service.

38. An insured person, moreover, has an obvious right to complain if he experiences undue difficulty in securing acceptance by any practitioner in his district at all, unless he has brought this about by placing himself in charge of an unqualified person and whilst he continues in such charge; and the arrangement made with the practitioners of an area must provide against an insured person being placed in this position.

39. Beyond his relationship to his patient as medical attendant the practitioner undertakes to keep certain records and make certain reports and also to furnish certain certificates. Statements made in such records, reports, or certificates about a patient's condition are matters of professional judgment, and, if honestly made, should not render the practitioner liable to any complaint beyond that to which all practitioners are liable in all their professional work, but wilful failure to keep records, make reports or furnish certificates on the occasions on which the practitioner has undertaken this duty, or the making of wilfully false statements in such documents, may well be the subject of serious official action.

40. If official complaints against an insured person were restricted to his failure to take action in the two ways judi-

cated in paragraph 37; and if official complaints against practitioners were restricted to the cases indicated above, it is probable that such complaints would not be numerous and liability to them would be recognised as on the whole just. It is probable, too, that the machinery at present provided for dealing with such complaints would, with some minor adjustments, be considered to be not inappropriate in the majority of cases. It is suggested, however: (1) that all complaints against a practitioner should in the first instance be sent to the Chairman of the Local Medical Committee and the chief administrative medical officer of the local authority (mentioned in paragraph 46); (2) that only such as could not be settled by them with the acquiescence of both parties should proceed further; (3) that questions of general conduct, detrimental to the service, or of giving false certificates should be reported upon in the first instance by the Local Medical Committee; (4) that an appeal to the Courts should be possible not only on the ground of improper procedure as at present, but also on the ground that the penalty inflicted was out of proportion to the offence; (5) that in the case of proposed removal from the service the practitioner should have the right of appeal to a duly constituted central professional committee, and that the Minister of Health, in cases where this right was exercised, should not be able to remove the practitioner from the service unless the central professional committee advised this course.

41. The circumstances of medical practice are so diverse in different parts of the country that any absolutely uniform regulations or terms of service are very difficult of application in some respects and in some areas. Particularly do the conditions in sparsely-populated districts need special consideration. It is, on the other hand, undesirable that similar conditions in different geographical areas should be differently dealt with, and, indeed, that there should be any unnecessary variety in the conditions or terms under which practitioners serve. It is suggested, therefore, that in the official regulations and terms of service there should be in some sections alternative provisions which might be adopted in certain districts or even in individual cases. Evidence as to special conditions in (a) sparsely-populated rural areas, and (b) certain colliery areas, will be found in Appendices I and II.

42. There is one anomaly in the arrangements for the provision of medical benefit created by Section 15 (4) of the 1911 Act (Section 24 (4) of the 1924 Act) which the Association is of opinion should now be rectified. The Section in question of the 1911 Act recognised certain medical aid institutes existing at the passing of the Act as agents for the administration of Medical Benefit (including the provision of any necessary drugs and appliances) for their members. The term "Medical Aid Institute" is a generic title which covered Friendly Society Institutes, Workmen's Medical Aid Associations, Workmen's Medical Funds and certain Provident Dispensaries—all now known under the style of "Approved (15 (4)) Institutes." It is believed that all these institutions employ whole-time medical officers paid by a salary, whose appointment and control is entirely in the hands of the governing body of the institute—a purely lay committee. The Association is of opinion that the standard of treatment given by these institutions is not equal to that given by the insurance service as a whole; it is certain that the great majority of medical men decline to take service under the conditions laid down by these institutions and it is difficult to argue that they supply any such need of the community as justifies their being placed outside the general scheme of administration of medical benefit.

#### SECTION D. ADMINISTRATION.

43. Two of the main principles to be satisfied in the administration of a National Health Insurance scheme seem to the Association to be these: (1) that the medical benefits in the widest sense (including the "treatment benefits" at present provided and administered by some Approved Societies) should be regarded as a health service and administered along with other health services, distinct from the administration of any cash benefits which should themselves be administered either separately or along with other cash benefits available from other schemes of National Insurance, and (2) that in the administration of the health services provision should be made for participation of the medical profession to an adequate extent. In Appendix III will be found a statement as to the points in connection with one of the "Additional Benefits," namely, Ophthalmic Benefit.

44. The central administration of all health services should be under the control of the Ministry of Health, and the local administration of all these services should be in the hands of a local authority established ad hoc, or acting through a statutory Committee constituted in accordance with schemes—

all of which should provide for a proportion of membership of persons of experience in health matters, including representatives of the medical profession. Such committees would be analogous to the existing statutory Education Committees of local authorities. It is recognised that existing local Government areas are in many cases not ideally the best for purposes of health administration, and that altogether new areas centred in each case round a considerable town, would be more satisfactory for purposes both of health and of education. Of existing authorities, however, it is probable that County Councils and County Borough Councils would be found the least unsuitable, though in a few cases it might be preferable to group a few Borough or Urban District areas.

45. In any case such unification of medical services as those contemplated in this Memorandum would, in such an administrative system involve the disappearance as such of Insurance Committees and the transfer of the health functions of the Poor Law Guardians. It is certain, however, that many of the members and officers of these bodies would be indispensable for the work of the unified authority.

46. Each such Authority would have a Chief Administrative Medical Officer, who would no doubt in most cases be the existing Medical Officer of Health. In each area there would be also a Statutory Local Medical Committee elected or appointed under a scheme which would ensure that it was representative of all kinds of medical practice in the area. Such a medical committee would take the place of both the existing Panel Committee and the existing Local Medical Committee, and like the former of these but unlike the latter, would have funds provided for administrative purposes. The duties of this Committee would be to appoint the representatives of the medical profession on the Local Health Committee and on any other local committees containing such representatives, to conduct any negotiations with the local health authority on behalf of the profession, to advise that authority on purely professional matters and to perform any other statutory duties imposed upon such a Medical Committee. The Medical Committee should have the right to present its view not only to the Local Health Committee but also to the Ministry of Health and to the public. A separate Dental Committee would probably be required.

47. The administration of the cash benefits (sickness disablement, maternity) does not primarily concern the medical profession as such. Practitioners are, however, brought into close and important relationship thereto by reason of the facts; (1) that they have to give medical certificates on which to a large extent the payment of these cash benefits depends; (2) that they often find their patients in doubt, difficulty or even distress with reference to these payments; (3) that they, through the Insurance Committees, are largely dependent on the bodies which administer these benefits for the correctness or otherwise of the lists of insured persons for whom they are responsible.

48. Evidence of serious imperfections in the administration of Approved Societies both in notifying Insurance Committees of the enrolment of insured persons and of the suspension of their members from medical benefit, and in the payment of sickness benefit to their members is continually coming to the notice of practitioners in their daily work, but except as to one matter on which there are official statistics of great importance, the Association does not wish to stress this. Doubtless, as in the corresponding matter of the imperfections of medical attendance and treatment, a considerable proportion of the complaints are vague and incapable of being substantiated, or are really due to faulty action on the part of the insured persons themselves. Doubtless, too, there are a considerable number of agents of large societies and a number of part-time officials of small societies who are unable to understand, or do not take the trouble to understand, the regulations under which they work or the instructions of their superior officers, just as there are some practitioners who will not read or consider memoranda or communications addressed to them. Doubtless, again, as in the case of medical attendances, the proportion of cases in which there is cause for complaint is quite small in relation to the total number of occasions on which complaint might possibly have arisen. Nevertheless it is distressing to doctor as well as to patient to witness cases in which actual want arises and delay in recovery ensues owing to the non-payment or the delay in payment of benefits to which the insured person appears entitled; and there is much loss of valuable time in explaining to such persons what they should do in order to secure what they believe to be their rights or to what quarter their complaints should be addressed.

49. The matter of the delay of Approved Societies to notify promptly the fact that members have passed out of medical

benefit or issue orange slips notifying suspensions from medical benefit is, however, serious. The following extract is from the official Memorandum (C.I.C.I.) issued to Approved Societies by the Central Index Committee in March, 1923:—

21. *Delay in issue of Orange Slips.*—The suspension from medical benefit which requires to be notified by the issue of an orange slip arises out of circumstances which should be known to the Society some considerable time before the suspension is due to take effect, and in the case of employed contributors usually about six months before that date. The instructions require that the Society should issue the orange slip as early as possible in the half-year at the close of which the member is due to be suspended. This, again, is no mere formality; it is necessary in order that the orange slip may be forwarded to the Insurance Committee before the suspension actually takes effect so that the member may be removed from the doctor's list immediately he ceases to be entitled to benefit. Doctors are credited on the numbers upon their lists at the beginning of each quarter; and it follows that if the Insurance Committee is unable to remove a suspended member from his doctor's list by the first day of the ensuing half-year, the doctor is credited for a further quarter at least in respect of that member, while the member himself may enjoy a period of medical benefit beyond that to which he is entitled.

22. Notwithstanding, however, the practical importance of the prompt despatch of orange slips, much delay is experienced by the Central Index in receiving them from Societies. The orange slips received notifying suspension on 30th June, 1921, for example, numbered 275,000, of which no more than 100,000 were received in time to permit of their being dealt with before the date of suspension, the balance of 63 per cent. of the persons concerned being still credited to doctors after ceasing to be entitled. In the case of suspensions taking effect on 31st December, 1921, 474,000 orange slips were received, of which 250,000 only were in time to be dealt with by the date of suspension; while of the suspensions taking effect on 30th June, 1922, 326,000 were received, of which 223,000 alone could be dealt with before the date of suspension.\*

23. It will thus be seen that in practice a large proportion of the orange slips issued are despatched too late to be made effective by the date of the suspension which they are intended to notify; and the consequence of this delay is, as already indicated, that hundreds of thousands of insured persons are in a position to obtain benefit beyond the period for which they are entitled to receive it, while credit for them is unavoidably given to the doctors concerned for a full quarter at least beyond the date of suspension, irrespective of the date when the numbers are actually taken off the doctors' lists. Some substantial improvements can reasonably be expected in this connection; and apart from the consequences just indicated, the Central Index Committee think it necessary to point out that delay of this kind is bound to increase the administration expenses of the Index. If all orange slips were forwarded promptly by each Society in the early part of the half-year at the end of which suspension is due, or in the case of large societies issued in equal instalments at regular intervals throughout that half-year, the heavy work of handling them and passing them on to Insurance Committees could be overtaken with an even load of work. If, however, receipts of orange slips are, as at present, congested towards the end of that half-year, extra expense is incurred through the dislocation of the current work or the employment of extra staff to cope with the congestion.

\* The figures in this paragraph relate to England.

This shows that in a period of eighteen months as the direct result of imperfect administration on the part of approved Societies there were 503,000 persons whom doctors were liable to attend in respect of whom no contribution was forthcoming, and there are figures showing that in Manchester alone there were such persons actually receiving treatment as follows:—During the last two quarters of 1921, 252; first three quarters of 1922, 758; whole of 1923, 1,190; and during the first two quarters of 1924, 311.

50. The profession regards the question of medical certification as of the highest importance, and looks upon the issue of a false certificate as one of the gravest offences of which a practitioner can be guilty. There has, no doubt, from time to time, been a certain amount of lax, as distinguished from wilfully false, certification on the part of some practitioners,

and some disregard of certification rules which, since they were in force, should have been strictly obeyed. In practice, however, it is difficult sometimes to obey all these rules quite strictly without doing some injustice to the insured person, and many of the conclusions which have sometimes been drawn by the officials of Approved Societies from an examination of large numbers of medical certificates or from the results of reference to Regional Medical Officers are erroneous, due often to very natural misinterpretation or misunderstanding. It is recognised that bodies responsible for the administration of cash benefits have a right to be consulted with regard to the arrangements for certification and to criticise the working of such arrangements, and the Association is prepared, should the Royal Commission wish it, to go more fully into the question of certification and to reply to any allegations which may possibly be made with regard thereto; but it appears that, in the main, medical certification in relation to sickness benefit is remarkably well done, and certainly an immense amount of trouble is taken to do it conscientiously and accurately, in spite of some failures.

51. Some alterations in the forms of certificate and of the Certification Rules and arrangements would conduce to the easier and more harmonious working of the system, and would be for the convenience alike of doctor and patient, without seriously interfering with the rights of the bodies administering cash benefits. For example, the phrase "incapable of work" used in the Acts and therefore necessarily repeated in all certificate forms is misleading and inaccurate if the words are given their ordinary signification; and certificates containing this phrase can be signed honestly only because the words are now understood to have a technical meaning, which, however, needs a pamphlet to set forth accurately. It is desirable that this phrase should be altered. With this exception the form of the first and of the final certificates might remain as at present, and it is probable that a First Intermediate Certificate may properly be required under the same conditions as now; but with regard to other intermediate certificates it is suggested (a) that they should simply state that the practitioner has seen the patient on a particular day and that the patient remains unfit for work; (b) that the interval between the issue of such certificates should be at the discretion of the practitioner provided that such interval was not greater than 14 days in the case of Sickness Benefit nor than 42 days (or in rural areas three months) in the case of Disablement Benefit; (c) that the practitioner should be able in the former case to apply for permission to make the interval longer than 14 days, and that the body administering Disablement Benefit should be able in the latter case to ask that the interval should be made shorter than 42 days or three months, as the case may be; (d) that the arrangements for special intermediate certificates dealing with absence from home should be more elastic both as to the period of illness at which such certificates may be issued and as to the length of time for which they should be available.

52. In the event of the complete separation of the administration of medical benefit from that of cash benefits which is suggested, the method by which these cash benefits shall continue to be administered is not the concern of the profession. Many practitioners, however, hold the belief, based on experience, that this administration is likely to be more satisfactory and sympathetic in the hands of certain classes of Approved Societies than in the hands of a large State organisation or committee of a local Government Authority. If it is determined that Approved Societies shall continue with this administration as one of their functions it is suggested that there should be certain requirements which all such societies should meet. They should (1) be of such a size as would constitute a properly insurable group; (2) be of such a character (or have such financial arrangements made for them by consent) as will not vitiate a uniform insurance scheme; (3) be of sufficiently uncomplicated constitution so as not to put their members at a disadvantage; (4) be obliged to classify all their members on a territorial basis; (5) be as uniform as possible in their rules for the conduct of insured persons.

53. The profession is completely convinced, in consequence of intercourse with insured persons over a period of twelve years, that Approved Societies, as at present constituted, do not as a whole in any sense represent insured persons, their wishes or opinions. For the most part insured persons take not the slightest interest in the work of their Societies, and very often do not know the name of the Society to which they belong. This indifference is probably inevitable in the case of the larger Societies, and of the great majority of insured persons and does not necessarily indicate any lack of interest or ability or zeal on the part of the principal officials of such Societies.

## SECTION E. REMUNERATION.

54. The remuneration of members of the medical profession working under the National Health Insurance scheme should be determined on its merits by negotiation between the Ministry of Health on the one hand and a central body representing the profession on the other. Such central body might most properly be the Council of British Medical Association, representing, as it does, all branches of the profession through its Divisions and Branches, and the Local Medical Committees of the country through its Insurance Acts Committee. The Association is strongly of opinion that the remuneration of the general practitioner service should be by a capitation system, though local option might be allowed as now in the distribution of the amount allotted in each area. The remuneration of consultation and specialist work, on the other hand, must necessarily be by tariff fees according to the variety of service rendered, or in some cases by sessional fees according to the time given and character of the work done.

55. The amount of the central practitioners fund must necessarily be arrived at by a somewhat elaborate actuarial calculation since it is impossible accurately to count the insured population day by day. The distribution of this pool to the different areas, too, must be made by a small expert Committee who will take account of all relevant facts. In the past there have been great difficulties in both these calculations, and it is desirable that the profession should be completely assured that any margin of error is reduced to a minimum.

56. The principle on which the amount of the remuneration should be established is that it should in total compare not unfavourably with that which should be forthcoming from similar responsibility and work in private practice of a like nature among the same class of persons, allowance being made for security on the one hand, and on the other hand for work done not primarily for the individual patient but for the State or public body.

57. The actual amount of the capitation fee on which remuneration for the general practitioner service should be based has been so recently and so fully argued, before the Court of Enquiry in January, 1924, that the profession has no wish to re-open the matter at the moment. They are, however, convinced (1) that the capitation fee of 9s. is still too low to be a proper remuneration for the responsibilities undertaken and work done under the insurance scheme; (2) that the extra amount allowed for rural conditions requires reconsideration. The exact determination of this matter, however, and the appropriate tariff of fees for consultant and specialist services must depend largely upon the nature of the insurance scheme recommended by the Royal Commission and enacted by Parliament. It is, therefore, not possible with advantage to carry it much further at the present time.

## APPENDIX I.

## MEMORANDUM AS TO SPECIAL CONDITIONS OF INSURANCE PRACTICE IN RURAL AREAS AND THE EXTRA REMUNERATION CALLED FOR TO MEET THEM.

1. Any consideration of the special conditions of rural practice was specifically excluded from the Reference to the Court of Enquiry into Remuneration in January of this year. It therefore becomes necessary to go somewhat fully into this aspect of the question before the Royal Commission. The importance of the matter to the profession is evidenced by the fact that in 1923 of 12,711 insurance practitioners there were 5,649 (40 per cent.) who claimed mileage, and therefore to some extent were practising under rural conditions.

2. There are certain undeniable peculiarities in these conditions to which the attention of the Ministry has already been drawn, and which have been acknowledged by them as worthy of consideration. They may be summarised as follows:—

- (i.) The list of a practitioner in a sparsely populated district must necessarily be smaller on the average than that of one in a town;
- (ii.) The cost of travelling and the time occupied in travelling is much more in the country than in a town;
- (iii.) The facilities for lightening the work of the practitioner (e.g., nursing and hospital facilities) are less in the country than in the town;

(iv.) The proportion of visits to attendances at the surgery is higher in the country than in the town, and the time occupied in rendering service is longer;

(v.) The necessity to engage a *locum tenens*, even for a short absence from home, whether for holiday, study, or professional business, presses hard on the country doctor, since deputising arrangements such as are the custom in the towns, are impracticable;

(vi.) The absence of day schools and of practically any higher education facilities in the more rural districts adds very materially to the country doctor's domestic expenses.

3. With regard to (i.), the average number of insured persons on the lists of the doctors who claim mileage is 697, that on the lists of all other doctors is 1,200. The doctors claiming mileage include many town practitioners who have a few patients in the country, and if these were excluded it is probable that the genuine country practitioner would be found to have an average of between four and five hundred, and that this list is incapable of increase. It may fairly be contended that a list of 500 people in a sparsely populated district takes at least as much time to work as one of a thousand in a town.

4. With regard to (ii.), since 1920 a mileage grant has been established to cover the cost of travelling beyond two miles from the practitioner's residence and a comparatively small addition was made in 1924 to meet the other conditions enumerated.

5. There is no doubt that at present owing to the unattractive financial conditions, rural practices are being abandoned in certain parts of the country. The difficulty is not confined to Great Britain and is perhaps inevitable, but if it is desired to retain efficient doctors in the country, it is absolutely necessary that their emoluments should be such as will enable them to maintain in all essentials a suitable standard of life.

6. The best solution would seem to be the retention of the present system of a general capitation fee for the whole profession with augmentations to meet the special requirements of the rural practitioner.

7. Remuneration as expressed by the capitation fee has been approached in the past chiefly from two directions: (1) the value of work done for insured persons as measured by the time occupied in the services rendered—a certain net income for an average practitioner in full work being assumed—and (ii.) the value of services rendered as estimated by the fees commonly charged by general practitioners. Both these lines of approach would seem to point to the need for a supplementary fund for practitioners in rural districts, for (i) the time occupied in the same services is definitely greater under country conditions for the same number of patients, and (ii.) the fees charged both for visits and attendances at the surgery in country practices has always been of necessity higher than those in towns—a fact apparently left out of consideration in 1911, when the matter was investigated chiefly on urban data.

## APPENDIX II.

### MEMORANDUM AS TO SPECIAL CONDITIONS IN COLLIERY AREAS OF SOUTH WALES.

1. Section 16 (3) of the 1911 National Health Insurance Act (24 (3) in the Act of 1924) authorises the Insurance Committee to require any person whose income exceeds a limit to be fixed by the Committee and to "allow any other persons in lieu of receiving medical benefit under such arrangements as aforesaid, to make their own arrangements for receiving medical treatment and attendance . . . and in such cases the Committee shall . . . out of the funds out of which medical benefit is payable contribute . . . sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended in providing medical benefit for them."

2. In practically every area with the exception of South Wales this section of the Act has been taken to apply to individuals, but the Insurance Committees of Monmouthshire and Glamorgan have taken advantage of it to hand over the capitation fees for large bodies of workmen who have set up "Schemes" for the purpose of giving medical attendance by salaried doctors to the workmen and their families. The money for the families is obtained by deductions from the

men's wages supplemented by the money provided from Insurance funds under the above-mentioned section of the Insurance Act. The medical profession has always protested strongly against what it believes to be an abuse of the section, on the ground that these Schemes are an evasion of the intentions of the Acts which contemplates that the normal system will be the panel system, whereas these Schemes are worked on a whole-time salaried system.

3. The Schemes are invariably introduced and from time to time stimulated by a system of canvassing which is very unfair to competing doctors; they are controlled by Workmen's Committees, which are not responsible bodies like the Insurance Committee: they are subject to little or no central control they allow no direct representatives of the medical profession on them, nor are they guided, as the Insurance Committee largely is in medical matters, by a purely medical Committee—the Panel Committee. Experience has shown that the service provided is on the whole unsatisfactory as compared with that given by doctors under the normal system; the majority of these Schemes have disappeared after a comparatively short but unsatisfactory existence; and it is hoped that the Royal Commission will recommend such changes in the Acts as will make it impossible to finance such Schemes out of National Health Insurance Funds.

## APPENDIX III.

### OPHTHALMIC BENEFIT.

1. Among present "Additional benefits" dental and ophthalmic are easily first in demand and in value to insured persons.

2. Ophthalmic benefit appeals greatly to the insured person, for the symptoms of eye strain are most disturbing and are more frequent with the increasing complexity of modern life.

3. This benefit should be dealt with administratively in the way suggested in the main body of the memorandum with regard to the treatment benefits in general by being removed from the administration of Approved Societies. Under the present system, however, a few Approved Societies have made arrangements with specially qualified practitioners on behalf of their members and these arrangements are not open to the objection which is dealt with in the following paragraphs.

4. Other Approved Societies have entered into arrangements which are open to serious criticism and are certain to lead to grave danger to the insured persons.

5. These Societies have arranged for the provision of spectacles by opticians and without the necessary preliminary examination by a competent medical practitioner. The arrangement, it is alleged, is cheap. But cheap methods in dealing with human beings usually prove costly in the long run. It is sure to prove so in this regard, both immediately and in the future. An ophthalmic benefit secured through a competent medical practitioner is a full consultation covering external or internal diseases of the eye, refraction work, and vascular and neural examinations. The results of these examinations should be communicated to the insurance practitioner and would afford him information regarding his patients which he cannot get otherwise, and which will be a material guide to his work. The bare provision of spectacles by a "sight-testing" optician cannot secure these benefits, for he is not trained in the diseases of the eye and of the body which are concerned therewith. Apart from the risks inevitable in the employment of untrained or part-trained men for the examination of the most delicate sense organ and one closely connected with the brain, examinations by sight-testing opticians are inadequate and therefore unprofitable.

6. The utilisation of medical practitioners for this purpose will make it certain that within a very few years there will be a full supply of well-trained and competent ophthalmologists ready and able to do this work to the best advantage. If the employment of sight-testing opticians be continued or extended there will be a diminution of the supply of doctors willing to do this work, to the ultimate disadvantage of the community.

7. Further, as examination of the refraction of the eye for the purpose of fitting spectacles is regarded as a form of medical treatment, medical practitioners, with due regard to the disciplinary disabilities that would follow, or with proper regard for the welfare of their patients, cannot send their patients or be a party to sending their patients to persons not on the medical register.

[D.12.]

## QUESTIONS FOR MEETINGS OF THE LOCAL PROFESSION CALLED TO DISCUSS THE DRAFT MEMORANDUM OF EVIDENCE.

Most of the views expressed in the draft Evidence (D. 11) have been discussed and adopted from time to time during the past few years by the Representative Body or the Panel Conference, or both. Specific questions are in the main, therefore, only asked as regards the new suggestions. The meetings called to consider the draft Evidence are, of course, at liberty to express their opinion on any point mentioned in the report. It will be assumed that approval is given to all sections to which no objection is taken.

It is very desirable that the exact position of this draft Evidence should be clearly understood. The suggestions made on certain important new points, such as the extension to dependants, are not intended as declarations of policy, but as suggestions to the Royal Commission for their consideration. The profession will have to re-consider the whole position when the proposals of the Government, based on the Report of the Royal Commission, are placed before the country. It is therefore important that meetings should not bind their representatives down too rigidly, but, after stating their opinion on the points raised in the draft Evidence, send their representatives to the joint meeting on March 12th, 1925, for the purpose of so pooling the views of the profession throughout the country as to give the Royal Commission a clear idea of the present trend of medical opinion.

### QUESTIONS.

#### DEPENDANTS.

1. Is the Meeting in favour of the inclusion in an insurance scheme:—

- (a) of all dependants of all insured persons?
- (b) of the dependants of only the lower-paid persons included in the scheme described in paragraph 16?
- (c) of no dependants under any circumstances?

2. Does the Meeting consider that if any dependants are included it is essential to secure the provisions for lessening work as set out in paragraph 15?

#### POOR PERSONS NOT UNDER CONTRACT OF SERVICE.

3. Is the Meeting in favour of the inclusion of poor persons not under contract of service (para. 18)?

#### POOR LAW PATIENTS.

4. Is the Meeting in favour of the inclusion of that class of person at present attended under the Poor Law?

#### SPECIALIST AND CONSULTANT SERVICES.

5. Does the Meeting agree that the present service should at a convenient time be extended by the inclusion of specialist and consultant services (Section B)?

#### ORDER IN POINT OF TIME OF EXTENSIONS OF BENEFITS.

6. If financial or other circumstances should make it impossible at the same time to include dependants and also to extend the medical provision for insured persons to include specialist and consultant services, which would the Meeting put first—

- (a) the extension of the provision made for the present insured persons so as to include specialist and consultant services; or
- (b) the inclusion of dependants?

#### MATERNITY BENEFIT.

7. Does the Meeting agree with the inclusion of attendance at confinements and during the puerperal period together with

special examination and supervision during pregnancy being brought within the scope of the scheme under the conditions set forth in paragraph 29?

#### OFFICIAL COMPLAINTS.

8. Does the Meeting approve the somewhat altered procedure suggested in paragraph 40?

If not, what alternative proposals should be made?

#### GROUPING OF "ADDITIONAL TREATMENT BENEFITS" WITH MEDICAL BENEFIT.

9. Does the Meeting agree that it is essential that "additional treatment benefits" should be grouped with medical benefit and removed from the control of the Approved Societies (para. 41)?

#### ADMINISTRATION.

10. Does the Meeting agree with the suggestions contained in paragraphs 43 to 46 as regards the future administration of an extended National Health Insurance Service, in conjunction with the other health services of the country?

If not, what alternative is suggested?

#### CERTIFICATION.

11. Does the Meeting agree with the alterations in the rules of certification proposed in paragraph 51?

If not, state alternative suggestions.

Secretary of Local Meeting of Profession for \_\_\_\_\_

MEDICAL DEPARTMENT,

429, Strand, London, W.C.2.

January 2nd, 1925.

Last date for receipt of this form by Medical Secretary with Replies of Local Meetings of Profession—January 31, 1925.

[Notifications of meetings of the profession already arranged in various districts for the discussion of the Memorandum will be found at page 15.]

## PROCEEDINGS OF COUNCIL.

A MEETING of the Council of the British Medical Association was held on December 17th, 1924, at 429, Strand. Dr. R. A. Bolam presided, and there were present:

Mr. J. Basil Hall (President-Elect), Dr. H. B. Hall (President-Elect), Dr. G. Thomson (President-Elect), Dr. H. B. Hall (President-Elect), Dr. R. Wallace Henry (Immediate Past Chairman of Representative Body), Dr. C. O. Hawthorne (Representative Body), Dr. G. A. Allan, Sir Percy Bassett-Smith, K.C.B., G.M.C., Bailey, Dr. H. S. Beadles, Dr. J. W. Bone, G. F. Buchan, Dr. H. Guy Dain, Dr. J. S. Dalrymple, Dr. J. Don, Dr. C. E. Douglas, Mr. W. McAdam Eccles, Dr. David Ewart, Dr. C. E. S. Flemming, Dr. E. R. Fothergill, Dr. T. W. H. Garstang, Dr. J. Giansani, Dr. F. J. Gomez, Dr. F. W. Goodbody, Dr. T. Duncan Greenlees, Lieut.-Colonel C. B. Heald, R.A.F.(ret.), Dr. T. Eustace Hill, Dr. G. B. Hillman, Dr. I. W. Johnson, Dr. R. Langdon-Down, Dr. G. B. Hillman, Dr. I. W. Le Fleming, Dr. R. W. Leslie, Sir Richard Luce, M.P., K.C.M.G., Dr. A. Lyndon, Dr. J. A. Macdonald, Dr. S. Morton Mackenzie, Major-General Sir William Macpherson, K.C.M.G., A.M.S.(ret.), Dr. A. Manknell, Dr. Hugh Miller, Dr. Christine Murrell, Mr. A. W. Nuthall, Lieut.-Colonel F. O'Keefe, I.M.S.(ret.), Dr. William

Paterson, Dr. F. Radcliffe, Lieut.-Colonel J. W. F. Rait, I.M.S.(ret.), Dr. G. Sanders, Dr. J. W. Scharff, Mr. H. S. Souttar, Dr. John Stevens, Dr. W. E. Thomas, Dr. G. Clark Trotter, Mr. E. B. Turner, Sir Jenner Verrall, Dr. J. F. Walker.

#### Votes of Condolence.

The Chairman said that since its last meeting the Council and the Association had suffered serious losses in the death of Dr. Haslip, until lately Treasurer, and Dr. Crawford Treasure and Dr. Mactier, former members of Council. It was difficult to express the grief they all felt, particularly at the death of Dr. Haslip, who had endeared himself to them for so many years. Wellnigh half Dr. Haslip's professional life must have been spent in the service of the Association. His colleagues on the Council learned to love him, his memory would always be green amongst them, and the work he had done for the Association would remain and would help the Association in its future progress. Dr. Crawford Treasure and Dr. Mactier were not called to such high office as Dr. Haslip, but in their spheres they were very useful and well loved members of Council. Dr. Mactier in his own specialty was

always able to afford valuable advice, and in the case of Dr. Crawford Treasure the Council was well aware how heartily he had concerned himself in all matters affecting the profession, particularly in his own Principality, and also the Post Office medical service, in which he was much interested.

A vote of condolence with the families of these former colleagues was carried in silence, the members standing.

#### *Annual Meeting, 1925.*

The President-Elect (Dr. F. G. Thomson) had a motion that an official invitation be sent to the American Medical Association to nominate delegates to the Annual Meeting. Sir Jenner Verrall and Dr. Bristowe supported the proposal, which was carried unanimously.

#### *The Services.*

The Chairman, in calling upon Sir Richard Luce to present the report of the Naval and Military Committee, congratulated him in the name of the Council upon his election to Parliament.

Sir Richard Luce said that the first matter which had been dealt with by his Committee concerned the position in the R.A.M.C., which, owing to shortage of candidates, was steadily becoming worse. There was considerable discontent among the officers; seniors were called upon to do work which, if it were not for the shortage of candidates, would be done by juniors, and it did not appear that the block in promotion, of which the Committee had previously complained, had been removed. The Committee had made representations to the War Office and had had a meeting with the Director-General. He moved a resolution that a communication be sent to the War Office urging that (without prejudice to other matters which had been brought forward, notably the pay of majors) a higher rate of commencing pay should be offered. Sir William Macpherson said that the remedy for the discontent in the service would be largely met by securing that an increased number of newly qualified men joined the corps. He thought that the Association should use its influence with the medical schools to encourage entrance into the R.A.M.C. The resolution was agreed to.

Sir Richard Luce said that on the matter of the grievances of senior surgeon commanders, R.N., the Committee had at last brought the Admiralty to see that there was a case for remedy. The Admiralty had made to the surgeon commanders an offer of a lump sum of £250 to settle the grievances. While this, in the Committee's opinion, was far from adequate, it did vindicate the action which had been taken by the Association. Further negotiations were proceeding.

#### *Lunacy Law and Administration.*

Dr. Langdon-Down, Chairman of the Committee on Lunacy Law and Administration, submitted a draft of the evidence which it was proposed to give before the Royal Commission now sitting. It had been thought well not to deal with that part of the reference of the Royal Commission which concerned the care and treatment of patients actually in institutions, because another body—the Medico-Psychological Association—was dealing with that aspect of the question. The Committee also had not attempted to dictate as to the powers and duties of the authorities which supervised and controlled the arrangements for the reception of the insane, though at the points where these came intimately into touch with medical interests or the interests of patients some suggestions were offered. The Committee included members having a large variety of experience and an expert knowledge of lunacy law and administration, but the general view of the profession was also represented on the Committee, and, he thought, embodied in the proposed evidence. The Committee had recognized that there were two (not opposing) lines of thought with regard to the question, one of these having in view the patient as a private citizen who should be surrounded by all proper safeguards against abuse, and the other having in view the patient as a sick person, requiring earlier and better treatment. The memorandum endeavoured to incorporate and harmonize both these views.

The Chairman said that the document was a very technical one. The expert opinion must necessarily enter, and while he did not want to stifle criticism, he would deprecate lengthy discussion over details. Dr. Radcliffe suggested that for the magistrate to be required to interview the patient would sometimes be prejudicial to the patient, and, in certain distressing cases, repugnant to the patient's friends. He also referred to the paragraph which deprecated the continued detention in Poor Law institutions of persons of unsound mind, but the alternative was an enormous and impossible increase of county asylums. Dr. Fothergill brought forward several points on which, he thought, the document might be amended. Instead of the three-day urgency order, he thought the order should be for seven days, as this would often avoid the expense of a second medical certificate. He took exception to the phrasing of the absence of any reference to the teaching of medical students

and to early preventive treatment at an ordinary hospital. Dr. Langdon-Down said that the Committee fully sympathized with this last object, and he felt that this was conveyed in the memorandum directly or indirectly. If Dr. Fothergill would hand in his suggestions he would see how far they could be incorporated in the final memorandum.

Dr. Bristowe found fault with the section of the memorandum which favoured an interview with the patient by the magistrate in every case. The magistrate did not always exercise his judicial function in the way he should. Dr. Langdon-Down said that this difficult question had been considered at length in the Committee. The magistrate had the function of a judicial authority, and it was only consonant with that function that he should be able to weigh the evidence for himself. It was difficult, of course, to draw a distinction between the weighing of evidence and the forming of a medical diagnosis. While the Committee thought that the interview by the magistrate would be desirable, it did not lay this down in too positive terms.

The Chairman said that there seemed to be general agreement with the report; even the experts on this subject in the Council had taken no very grave exceptions, and he congratulated Dr. Langdon-Down and his Committee on an important piece of work.

The memorandum was approved, and Dr. Langdon-Down was given power to amend it in minor details. It was also agreed that the witnesses before the Commission should be Dr. Langdon-Down, Dr. J. W. Bone, Dr. F. H. Edwards, Dr. C. O. Hawthorne, Mr. E. W. G. Masterman, Dr. Christine Murrell, and Sir Jenner Verrall.

#### *Bureau for the Provision of Locumtenents.*

Dr. Morton Mackenzie, Chairman of the Organization Committee, brought forward a report on a matter arising from a resolution of the last Representative Meeting which referred it to the Council to consider the advisability of forming a "locum bureau," under the auspices of the Association, in each teaching centre. He said that although the office of the Scottish Committee had been used for this purpose, and the Newcastle-on-Tyne Division had been running a bureau of its own, what was now proposed was a new activity for the Association as such. At the Bradford meeting he had been against this proposal, but he had now come round to see its desirability, and his Committee was unanimous in recommending it. The reason which lay behind this departure was the necessity for the Association to do something for the newly qualified men and women. Recently the Association had agreed with the Society of Medical Officers of Health on a scale of salaries, and it had had to ask practitioners not to take up various appointments which conflicted with that scale; that being the case, it was felt that the Association ought to have something to offer them. A similar proposal was put forward at the conference with representatives of the teaching centres held in 1923. Another stimulus was the successful venture at Newcastle by Dr. Farquhar Murray, the honorary secretary for the Division. Manchester also had started a bureau of its own, but there it had been introduced under the aegis of the Local Medical Committee. Nothing expensive was proposed, at all events in the first instance—merely an organization for providing locumtenents in provincial centres. The Association was precluded from undertaking this work itself, and it would be necessary to proceed either by the registration of a statutory company under the Companies Act or to form a society under the Friendly Societies Act. The former was judged to be the better course. In forming the company wide powers would be taken, but that did not necessarily mean that anything more would be done than was indicated in the Bradford resolution. The one disadvantage of this new development was that it might be thought to trench upon the work of the medical agents, who had been of great help to the Association, especially in the matter of Warning Notices. He would regret this, but he thought that any antagonism would disappear as the project was better understood. The present proposal was to have only a co-ordinating office in London, and to have branches in the teaching centres. The benefits would be strictly confined to men during the first four years after qualification, and there would be preferential treatment for members of the Association in respect to the fees charged. He moved:

That it be recommended to the Representative Body that a bureau for the provision of locumtenents and assistants be formed under the auspices of the Association in such centres as may be deemed advisable.

After the Treasurer had spoken on the financial aspects of the matter, Sir Jenner Verrall said that the strongest point in favour of the Association at the moment was the rapid increase in its membership, but he did not think the young members would be retained or the proportion of newly qualified men joining the ranks remain at its present high level unless something of this kind were done. An amendment by Dr. Fothergill that the Branches and Divisions be urged to form such bureaux was lost by a large majority, and the recommendation of the

Committee was carried, together with some contingent recommendations reserving for future consideration certain questions relating to the activities of the Bureau.

#### Other Organization Matters.

A number of other proposals of the Organization Committee were agreed to, including, as a recommendation to the Representative Body, some new or amended Articles to further the affiliation arrangements between the Association and the Canadian Medical Association.

Another matter related to the grouping of Branches for election of members of Council. Dr. Mackenzie said that for a long time it had been felt that Wales ought to have another member on the Council, but to alter the grouping of Branches was a difficult matter. A way had now been found by asking Ireland to sacrifice one of its six members. Two Irish members on the Council, Dr. Darling and Dr. Leslie, acquiesced in the arrangement, and said that in their opinion Ireland was still sufficiently represented.

Dr. Mackenzie had once again the pleasant duty of reporting an increase in membership, which stood that day (December 17th, 1924) at 28,438, an increase of 2,314 on the figure for the corresponding date in 1923.

#### National Health Insurance.

Dr. Dain, Chairman of the Insurance Acts Committee, introduced the report of that Committee, which contained no recommendations.

Mr. Turner asked whether the Committee ought not to bring before the Council any principal resolutions of the recent Annual Panel Conference. Dr. Brackenbury quoted a minute of the Council in justification of the course which had been followed now for some years. He thought it would be a pity to insist that everything done at the Conference should be embodied in the Insurance Acts Committee's report to the Council. Dr. Fothergill thought that one fact which might have been reported was that the Conference unanimously approved the Association policy with regard to institutional treatment. Dr. Dain said that the Insurance Acts Committee was very anxious to hold the balance evenly as between its duty to the Council and its duty to the Conference, but the position was sometimes difficult to determine. Mr. Turner felt that the Committee was becoming less an integral part of the Association. The Chairman said that the reason why these matters were not reported to the Council was because, until this arrangement was made, the Council was flooded with matters which did not closely concern it.

The report was approved.

#### THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

##### Discussion on the Association's Evidence.

The draft memorandum of evidence to be submitted to the Royal Commission (see page 1) was next considered. The debate on this memorandum occupied the greater part of the remainder of the Council's sitting. As the matter was introduced by Dr. Bolam, Chairman of the Royal Commission Committee, Dr. Macdonald occupied the chair of the Council.

Dr. Bolam reminded the Council that the Committee which had had in hand the preparation of this evidence was one which included, besides members of the Insurance Acts Committee, representatives of other sections of the profession. It had had also the advantage of certain recommendations from the Non-Panel Committee. The result of several meetings of the Committee was the memorandum of evidence, which he hoped would be regarded as co-ordinating the views of the Insurance Acts Committee with those of the profession generally with regard to the wider aspects which opened out under the Royal Commission's consideration. For the drafting of the memorandum the Committee was very largely indebted to Dr. Brackenbury. It had been drawn up with the idea of dealing with the matter only along general lines, while in the oral evidence it would be possible for the Association's witnesses to speak out of their special information and experience. He noticed that evidence already tendered to the Royal Commission—notably approved society evidence—had been given in that fashion. The document now before the Council was an attempt to deal with a situation which was of most far-reaching importance for the medical profession. Nothing which the Association had touched during the years of its active connexion with its work involved more sweeping changes. The policy adopted must be well considered, and it was essential to endeavour to carry the general agreement of the profession—the unanimous agreement if possible. Dr. Bolam then went through the memorandum paragraph by paragraph, explaining briefly what was intended in each. When he came to paragraph 12, which dealt with the inclusion of dependants within the scope of national insurance, he said that this would probably be the most debatable in the whole document. The consequences to the profession of the inclusion of the dependants of present insured persons were pointed out. Another paragraph

which was the result of special consideration, in particular by Sir Ewen Maclean and his subcommittee, was that which dealt with the relationship of maternity work to an insurance scheme (paragraph 29). Another difficult paragraph (40) dealt with the procedure with regard to official complaints, and here it was suggested that in the event of a decision by the Minister to remove a practitioner from the service, the practitioner should have a right of appeal to the General Medical Council. He also drew attention to the skilful use which Dr. Brackenbury had made of a Government memorandum in paragraph 49, and with regard to the section dealing with remuneration he noted the explicit statement ruling out negotiation through approved societies.

Dr. Macdonald (from the chair) said that this document would go down to the Divisions for local discussion, and would afterwards come back to the Council. Was the Council prepared to approve it roughly at the present moment, knowing that there would be a later opportunity of revision, or did it wish a detailed discussion? If the latter, he could not forecast any reasonable limit to the length of the sitting. Dr. Bolam here drew attention to another document which had been circulated setting out the specific questions which it was proposed should be discussed at the local meetings of the profession. Of these, the question of dependants was the most debatable. Most of the other points set out in the memorandum had been already covered by previous resolutions, as, for example, the inclusion of specialist and consultant services, while other matters, such as the grouping of treatment benefits with medical benefits, were not likely to furnish occasion for any disagreement.

It was resolved, on the motion of Dr. Fothergill, to discuss first the proposed time-table, and afterwards to discuss the memorandum.

Dr. Bolam then moved the adoption of the following time-table:

1925.

- Jan. 1st to 25th.—Meetings of local profession called conjointly by the Secretaries of the Divisions and Local Medical and Panel Committees.
- Jan. 31st.—Last date for receipt of replies of local meetings of profession.
- Feb. 5th.—Joint meeting of Royal Commission and Insurance Acts Committees to consider replies.
- Feb. 18th.—Special meeting of Council, followed by issue of memorandum, revised, if necessary, in accordance with the views of the local meetings.
- Feb. 25th to March 5th.—Further meetings of local profession, called as before to instruct representatives prior to a central joint meeting.
- March 12th.—Joint meeting of the representatives of Divisions and of representatives of Local Medical and Panel Committees.
- March 25th.—Meeting of Council.
- April 4th.—Printed evidence submitted to Royal Commission.
- Any time after April 13th.—Witnesses to be heard by the Royal Commission.

Dr. Bolam said that the Committee believed these proposed steps to be adequate for bringing the subject before the profession. It would be disastrous if it became necessary to apply to the Commission for an extension of time. A special meeting of Council was to be summoned, and he thought this was well justified.

Dr. Fothergill thought that January was an unfortunate time for local meetings. His motion to vary certain of the dates, making them later, to admit of better local meetings, was not seconded.

Some questions arising on the status of the joint meeting of representatives of Divisions and of Local Medical and Panel Committees, to be held on March 12th, Dr. Brackenbury said that no one had thought of this meeting as including less than all those entitled to attend the meeting of the Representative Body and those entitled to attend the Conference of Local Medical and Panel Committees, and he thought it would be wise also to have any members of the Royal Commission Committee who did not come in either of those categories. He understood that Dr. Fothergill desired that in addition to this joint meeting there should also be a meeting of the Representative Body as such in order that that body might take its proper place in formulating the policy of the Association. But it was necessary to remember that these projected meetings were not for the purpose primarily of formulating policy, although that was involved to a certain extent, but for the purpose of formulating evidence which was to go before a Royal Commission, and there was a very important distinction between those two things. If something was advocated on behalf of the profession before the Royal Commission, and the suggestion was adopted by the Commission, and subsequently by Parliament, it would be difficult, if not impossible, for the profession to go back upon what it had put forward; but if the profession made suggestions which were not adopted, or if they made suggestions as provisos to certain other conditions which might be adopted with those provisos, and these conditions were adopted by the Commission without the qualifying provisos, it would be open to the profession to reconsider the whole position *de novo*, and to say that the proposals were unacceptable. It was important to remember how far in the

situations which might possibly arise out of this matter the Association had a free hand. Continuing, Dr. Brackenbury said that as Chairman of the Representative Body he would like to have some guidance. It seemed to him that it would be possible to constitute this joint meeting a proper Representative Meeting of the Association. The two constituents of the joint meeting—the Representative Body and the Panel Conference—would each have to hold a preliminary meeting separately and pass a resolution consenting to the joint meeting, and at all stages of the proceedings it would have to be possible for the two bodies to vote separately. He did not anticipate any constitutional difficulty, but he would like to be fortified by the opinion of other members of the Council.

The Chairman said that there was no power in the Articles of Association to summon the representatives except to a Representative Meeting, which then became a meeting of the Representative Body.

Dr. Bolam pointed to an article (the second portion of Article 41) which in his opinion covered an emergency of this kind, and made it possible to defray the expenses of representatives attending such a conference. He was a little doubtful as to the policy of having these two bodies sitting side by side, each preserving its identity and passing resolutions which would have to come to the Council. That way might lead to a cleavage. The bond between the Association and the Panel Conference organization was of a rather curious character, but it had stood the test of time, and he believed the cohesion now was better than ever it had been. He would deprecate anything which emphasized the distinction, and his suggestion would be that this should have the character of one united meeting, not a meeting of two sections, the differences between which might in that case find undesirable emphasis. He did not believe that there were likely to be great divisions of policy; the most debatable point was this question of dependants. He thought that the Representative Body might be safely trusted at a later stage to implement what had been done.

Mr. Turner said that the proposed joint meeting would be, practically, a meeting of the Representative Body, heavily diluted by the Panel Conference. But how many of those attending such a meeting would represent practitioners not working the Act? The ideas of these men must be taken into consideration, and the feeling of the whole profession would not be voiced. Dr. Brackenbury pointed out that the meeting would have been preceded, and if necessary would be followed, by local meetings of the whole profession. He further made it plain that he did not differ in the least from the position which Dr. Bolam had just made clear as to the desirability of one united meeting. Dr. Bolam said that the constitutional way of dealing with the situation would be to summon the Representative Body, and at its assembling to put forward only one piece of business—that of authorizing every representative to sit in the ensuing conference. He took it for granted that every member of the Council who was not already included as a member of the Representative Body or of the Panel Conference would be asked to attend. Dr. Brackenbury proposed an addition to the recommendation with regard to the joint meeting, that those attending should include other members of the Council, the Insurance Acts Committee, and the Royal Commission Committee. Dr. Fothergill seconded this amendment, which was carried, as was also the whole of the recommendation dealing with the time-table.

The Council then returned to the recommendation to approve the draft memorandum and to issue it forthwith to the Divisions and to Local Medical and Panel Committees.

Dr. Brackenbury said that he thought all would agree, whatever individual opinion there might be in the Council on the matters at issue, that it was desirable to take the views of local meetings of the profession. He thought it right that the Council should be asked—he was speaking more particularly of paragraph 12, dealing with dependants—to endorse the lead given to the profession by the Committee. There were two propositions in this paragraph: one that the whole of the dependants of insured persons as at present defined should not be included, and the other—a much more difficult proposition—that after a line had been drawn the dependants of insured persons below that line—that was to say, dependants of the lower-paid insured persons—should be included in an insurance scheme. If this was practicable administratively and financially—and that was for the Royal Commission and Parliament to say—the Committee believed that it would be good for the nation, and not impossible for the profession. It was out of the question for witnesses on behalf of the Association to maintain the proposition that from the national health point of view it was good to have these lower-paid insured persons included in national insurance, but that no provision should be made for their public health services in the direction of the establishment of treatment clinics under the auspices of local authorities, and the private practitioner and destroy the economic independence of the profession. The only way to meet such a development

was to substitute something better, and to say that the people for whom this clinic treatment was provided should be provided for in a far better way, by having a practitioner of their own under the national insurance scheme. He would not minimize the difficulties, nor the fact that the volume of work imposed upon practitioners under any such arrangement would be great. Mr. Turner asked how the "lower-paid insured persons" would be determined, and how many dependants such a proposal would bring in. Dr. Brackenbury said that he did not see how it was possible to determine them except by an income limit. It was almost impossible to say how many would be brought in under such a proposal. His own total figure, including existing insured persons, would be about 30 million.

Dr. Douglas said that he parted company from Dr. Brackenbury on one point. Dr. Brackenbury seemed to look upon the financial and economic side as one which could be safely disregarded. But this seemed to be the dominating fact of the situation. There was no doubt that the Government had in mind a very comprehensive "all-in" system of insurance. All the money the Government could find would be made available for that scheme, and there would be no money for any scheme such as that now adumbrated for dependants. He thought the Council was losing time in discussing insurance for dependants because it was not practical policy.

Mr. Turner referred to the difficulty of laying down any income limit. Such an income limit would be extremely unpopular among politicians. If it could be obtained he would be in favour of it, but he scarcely thought it possible. Again, if this proposal materialized it would mean, in a great number of instances, doing away with private practice. Practitioners in certain areas would do nothing but contract practice, and the division in the profession between those who did contract practice and those who did not would be deepened. By the suggestion that a very large proportion of the whole profession could be treated in this way, a distinct incentive would be given to a State medical service, which some members of the Royal Commission favoured.

Sir Jenner Verrall said that if it came to a choice between an extension to dependants and an extension of benefits, he would favour the latter course. He thought, however, that if insurance were extended to dependants it would be quite justifiable and logical to extend it in the manner indicated in paragraph 12. Dr. Radcliffe said that he would be sorry if the Council came to a vote on the subject that day, for that would be to prejudice the position which the constituents of the Council might want to come to later on. Dr. Sanders, on the other hand, insisted that it was the plain duty of the Council to give a lead to the profession. This able document itself did not give a direct lead, but the Council, by the way in which it dealt with that document, could give such a lead, and this, he thought, it should do.

Dr. Le Fleming said that the only question to be decided was whether this was a suitable document to send down to the constituencies; the discussion must take place in the constituencies. Dr. Bolam said that the document, if passed that day, must be considered only as the provisional opinion of the Council; the formulation of a policy of the Association would come later.

Dr. Stevens said that, although he might be alone on the Council, he must register his protest against the strong bias of this document in favour of national insurance. It was not a properly balanced document; it failed to express the very large measure of disapproval on the part both of the profession and the public of the present conditions of medical benefit under the Insurance Act, and he moved that some words in that sense be included. Dr. Brackenbury replied that to include such words would be to throw the whole document out of gear. The resolution referring to the measure of success which had attended the experiment of national insurance was carried unanimously by the Panel Conference, and by more than the requisite majority in the Representative Body. Mr. Turner, while agreeing with the terms of the amendment, thought it would be unwise to press it, and Dr. Stevens said that he was quite content, having voiced this feeling, to withdraw the amendment.

Dr. Beadles, with the object of obtaining a vote in the Council on the principle involved, moved the deletion of paragraph 12 ("Dependants"). Dr. Goodbody seconded. The proposition was lost, 11 voting in its favour and about 25 against.

The document was then discussed page by page.

Mr. Turner moved, and it was agreed, to omit a reference to the hawk and small tradesman as examples of the "poor persons not under any contract of service," as described in paragraph 18.

Dr. Dain thought that it was not made sufficiently clear, in the section dealing with the extent of the provision to be made, that all insured persons should be entitled to equal treatment benefits. It was agreed to amend the document to give this point greater emphasis.

Dr. Douglas pointed out, with regard to paragraph 29, that maternity work had always been outside insurance practice. It was not a question of payment, but of imposing a very difficult and responsible duty upon the practitioner. Dr. Brackenbury said that the definite resolution embodied in this paragraph was passed, he thought unanimously, by the Panel Conference and reported to the Council. It was the opinion of that Conference that something more than cash provision ought to be made for the wives of insured persons in respect to maternity. The present proposal would make the provision of a midwife for the insured woman part of the insurance scheme. Dr. Radcliffe opposed the paragraph, which, he said, would have the effect of bringing doctors under disciplinary powers in connexion with midwifery. Dr. Bolam held that the mere deletion of the paragraph would leave matters in a very awkward position. The profession had allowed itself to drift into a peculiarly difficult position with regard to midwifery, and the paragraph was really an attempt to arrive at the greatest common measure of agreement. Sir Jenner Verrall hoped the Council would not delete the paragraph; some statement in the document on this very important question was clearly desirable, but he thought it would be better to say in what particular and definite manner the Council thought some additional provision should be made. A motion to delete the paragraph was lost.

Dr. Bone desired that the provision for a woman within the insurance scheme should include attendance by a practitioner or registered midwife during labour. Dr. Brackenbury pointed out that a very large proportion of confinements—Dr. Bone gave the figure as 56 per cent., but Dr. Brackenbury thought it was higher—were attended by registered midwives, and if Dr. Bone's proposition were adopted the State would ask why, having financed a scheme which had worked without disaster, it should go to the trouble of financing something else which was in the nature of a luxury. It would involve the State in a big expenditure which the State had already demonstrated to be unnecessary for the national health. For his own part, so far as normal labour was concerned, he was in favour of the trained midwife as against the practitioner *plus* the "handy-woman." Dr. Dain hoped the paragraph would remain as at present. The provision of doctor and midwife would mean that insurance practitioners would practically be compelled to attend all confinements, for nearly all insured women would avail themselves of the opportunity of securing the attendance of a doctor. After some further discussion, the paragraph was left as originally drafted.

Mr. Souttar desired the addition to paragraph 31, dealing with residential institutional treatment, of some words putting forward more strongly the hospital policy of the Association, and this suggestion was accepted by Dr. Bolam.

A discussion arose on paragraph 40, in which it was laid down that in a case of removal from the service a practitioner should have the right of appeal to the General Medical Council. Mr. Eccles asked whether the General Medical Council had powers to carry out what was now suggested. The Chairman agreed that it might require an Act of Parliament.

Dr. Lyndon proposed the deletion of this subparagraph, arguing that an appeal to the courts, as provided in the previous paragraph, was all that need be claimed. Dr. Brackenbury said that the functions of the General Medical Council in this respect would be advisory. Mr. Turner favoured the setting up of a professional committee, which should be constituted to act judicially. The Chairman reminded the members that the General Medical Council was constituted, not for the protection of the profession, but for the protection of the public. The proposal to delete this subparagraph was lost, and Dr. Fothergill then moved to substitute for the words "General Medical Council" "a duly constituted central professional committee," and this was carried.

Dr. Bone moved to delete an introductory paragraph in the section on remuneration—a paragraph which discussed the financial aspects of what was proposed. It seemed to him idle to urge that, although large numbers of dependants were to be brought in, and various extensions made in the service, the scheme could be financed without much additional contribution. Sir Jenner Verrall seconded the proposal to delete this paragraph, on the ground that either the question of finance ought not to be touched at all in the memorandum or ought to be dealt with in a much stronger fashion. Dr. Brackenbury reminded the Council that for many years the true position with regard to national health insurance funds was not publicly disclosed. Only when the Association itself instituted expert inquiry was it discovered what a large amount had accumulated in the fund. He proposed, however, to incorporate in the paragraph the words "with a small contribution for additional persons who come into the national scheme." The Medical Secretary suggested that a competent statistician should be asked to explore the position with a view to seeing whether the paragraph could be supported by actual figures. It was agreed

that this course should be taken, and in the meantime the paragraph was held back.

Dr. Fothergill, with regard to the final paragraph on remuneration, thought that it should be open to Dr. Brackenbury to attach other arguments in favour of the position set out in that paragraph with regard to the capitation fee. Dr. Brackenbury said that all that had been done here was to enter a caveat that if the system was to be continued on the present lines the profession was prepared to argue for a higher figure than 9s.

The remainder of the document was then agreed to as material to be sent to the Divisions, and the document containing the questions proposed to be issued to meetings of the local profession was also adopted (see page 9).

Dr. Flemming, amid general applause, congratulated the Royal Commission Committee on the issue of the memorandum. It was a statesmanlike document, and he doubted whether the Council had ever had a document of quite this quality. He hoped the Divisions would duly appreciate this good and important piece of work.

Dr. Bolam then resumed the chair of the Council.

#### OTHER BUSINESS.

##### *Extension of British Medical Association Lectures to Overseas.*

Dr. Bolam, Chairman of the Committee which had had under consideration the extension of British Medical Association lectures to overseas, brought forward a recommendation that the sum of £400 which the Council had decided should be granted for 1925 for the provision of such lectures be increased to £450, and that the Science Committee be instructed that the extra money, together with any further sum resulting from economies which the Committee could introduce, should be allowed to accumulate with a view to utilizing it at intervals for the purpose of asking eminent members of the profession visiting the dominions to act as lecturers and meeting part of their expenses. The Finance Committee concurred, and the recommendation was agreed to.

##### *New Premises for the Scottish Office.*

Dr. Douglas brought forward a recommendation from the Scottish Committee that the Council should authorize the purchase of a house for the Association in Scotland at a price not exceeding £4,000. He said that the number of members in Scotland had very greatly increased during recent years, and it was practically certain that if good premises were obtained the number would increase further. The proposed new house was situated in one of the best parts of the capital, the accommodation was in every way suitable, and included a room for meetings.

The recommendation was agreed to. It was stated that the removal into the new house would take place at Whitsuntide.

##### *Part-time Prison Medical Officers.*

Mr. Turner stated that the Medico-Political Committee had been investigating complaints received from part-time prison medical officers. It appeared that insistence by the Prison Commissioners that all prisoners, as soon as possible after reception, should be inspected by the medical officer, had occasioned a great increase in the number of visits, which medical officers had to pay to prisons, particularly visits in the evening, besides the usual routine daily visits. The Council agreed that representations should be made to the Prison Commissioners that an addition of £100 a year should be made to the salary of part-time prison medical officers in respect of compulsory evening visits (to be retrospective from the time when the evening visits were insisted on); that this sum should not be in any way regarded as a bonus, but as an addition to salary for additional services; that each officer should be allowed to appoint a deputy to carry out these additional visits; that each officer should be allowed four weeks' annual leave, the Prison Commissioners making allowances towards the cost of providing the necessary accommodations; and that where officers had to attend police or assize courts they should receive a fee even though they were not called upon to give evidence.

##### *The Association's New Headquarters.*

Dr. Bolam gave a report of the progress of the work at the Association's new building in Tavistock Square. One question which came forward was that of the name for the new premises. The Office Committee considered that the name should be "The British Medical Association House," that the large conference room should be known as "The Great Hall," and the smaller room "The Hastings Conference Hall."

Dr. Douglas moved that the house be known as "Tavistock House," because of the many interesting associations of the building of that name formerly on this site. He disliked the clumsiness of the designation proposed by the Office Committee, and especially its crudeness if it were shortened, as it would be, to "The B.M.A. House." The Treasurer supported the Office

Committee's proposal. He felt sure that whatever designation were given the house would popularly be known as "The B.M.A. House," just as St. Stephen's Palace of Westminster was scarcely known by that name at all, but as the Houses of Parliament. Dr. Bolam pointed out some postal and other difficulties, and added that the Building Committee proposed to take out some of the foundation of the original Tavistock House, and from that material to erect in the garden something in the nature of a memorial with a tablet recording the connexion of the house with Charles Dickens. Dr. Douglas's amendment was lost, and the original recommendation to call the house "The British Medical Association House" was adopted.

The Council transacted other business, and rose shortly after 8 p.m.

## British Medical Association.

### CURRENT NOTES.

#### The Sir Charles Hastings Clinical Prize for General Practitioners.

The Council of the British Medical Association has decided to establish experimentally an annual prize—"The Sir Charles Hastings Clinical Prize"—of fifty guineas for an essay or lecture for the purpose of stimulating systematic observation, research, and record in general practice. The Council believes that systematic observation by general practitioners, along selected lines of clinical study, may result in the production of practical contributions of great value by those who are in a favourable position for following disease through its various stages.

The first prize will be awarded in 1926, and the conditions governing its award, as adopted by the Council on April 16th, 1924, are as follows:

#### Regulations.

1. This prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experience of the candidate collected in general practice, and a high order of excellence will be expected. If no essay entered is of sufficient merit no award will be made.
4. Essays, or whatever form the candidate desires his (or her) work to take, must be sent to the Medical Secretary, British Medical Association, 429, Strand, W.C.2, not later than December 31st, 1925, and the prize will be awarded at the Annual General Meeting of the Association. The first award will be made in 1926.
5. If any question arises in reference to the eligibility of the candidate or the admissibility of his essay, the decision of the Council on any such point shall be final.
6. Each essay must be distinguished by a motto, and must be accompanied by an envelope marked with the same motto and including the candidate's name and address.
7. The candidate who gains the award shall, if the Council so desires, publish his paper in the *BRITISH MEDICAL JOURNAL* or deliver a lecture on the subject thereof at a meeting of the Association.
8. Inquiries relative to the prize should be addressed to the Medical Secretary, 429, Strand, London, W.C.2.

#### The British Medical Association Staff.

On Wednesday, December 24th, the members of the clerical and printing staffs of the British Medical Association held their Christmas luncheon in the staff luncheon room. Mr. S. Coulson, chairman of the Staff Committee, presided, and welcomed the guests, who included the Editor (Sir Dawson Williams), Deputy Medical Secretary (Dr. Anderson), Assistant Medical Secretary (Dr. Lord), Intelligence Officer (Miss Lawrence), and the Sub-Editor (Dr. Griffin). Apologies for absence were announced from the Medical Secretary (Dr. Cox), the Financial Secretary and Business Manager (Mr. Ferris-Scott), the Assistant Editor (Dr. Horner), and Assistant Medical Secretary (Dr. Macpherson). Sir Dawson Williams, after expressing the thanks of the guests for the hospitality received, gave

some interesting stories regarding the dining habits of the Emperor Napoleon. Dr. Anderson, who also spoke, referred to the great benefit conferred by the establishment of the staff luncheon room in fostering good fellowship among the staff. He read a letter addressed by Dr. Cox to Mr. Widdeson, honorary secretary of the Staff Committee, expressing his regret at being unable to be present and acknowledging with thanks the good work done by the whole staff on all occasions, and especially in emergencies. In referring to the new home of the Association, Dr. Anderson said that the accommodation to be provided there for the staff luncheon room would be much larger than that at present enjoyed.

## Association Notices.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISIONS.**—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, January 22nd, when Dr. K. D. Wilkinson will speak on cardiac irregularity.

**BIRMINGHAM BRANCH: WEST BROMWICH DIVISION.**—The annual meeting of the West Bromwich Division will be held at the offices of the Smethwick Insurance Committee, 1, South Road, Smethwick, on Tuesday, January 6th, at 3 p.m. Business: Summary by the Chairman of the work of the Division during the past year; election of officers for 1925; to consider the draft Memorandum of Evidence to be put before the Royal Commission; the Chairman-Elect, on assuming the chairmanship, will give an inaugural address on the reduction of maternal and neo-natal mortality.

**ESSEX BRANCH: NORTH-EAST ESSEX DIVISION.**—A meeting of the Division, to which all medical practitioners are invited, will be held at the Red Lion Hotel, Colchester, on Friday, January 9th, at 3 p.m., to consider the Memorandum of Evidence which is to be submitted in the name of the Association to the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. Alfred Cox, Medical Secretary of the Association, who will also be pleased to answer questions.

**GLOUCESTERSHIRE BRANCH.**—At the meeting of the Gloucestershire Branch to be held on Saturday, January 10th, Sir Humphry Rolleston, Bt., K.C.B., President of the Royal College of Physicians of London, will give an address.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—The next meeting of the City Division will be held at the Metropolitan Hospital on Tuesday, January 13th, at 9.15 p.m., when Mr. McAdam Eccles, M.S.Lond., F.R.C.S. Eng., will read a paper entitled "Lessons learnt from the chief skiagrams taken in my 'firm's' work during 1924 at St. Bartholomew's Hospital," illustrated by lantern slides.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—A meeting of the Lewisham Division will be held at the Parish Room, St. Laurence Vicarage, Catford, S.E.6, on Tuesday, January 20th, at 8.45 p.m., when Mr. Archer Ryland will read a paper on danger signals in the acute mastoid, illustrated by lantern slides.

**METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.**—A meeting of the Marylebone Division will be held at 8 p.m. on Wednesday, January 14th, at 11, Chandos Street, Cavendish Square, to discuss the draft evidence proposed to be put before the Royal Commission on National Health Insurance by the Association. This matter is of extreme importance to all members of the profession, as any contemplated changes will affect consultants, and members of hospital staffs in any capacity, medical officers of health, private practitioners not doing panel work, as well as the panel practitioners—in fact, every class of the medical community will be directly affected, many very adversely. Members and non-members of the Division are asked to attend this meeting.

**ESSEX BRANCH: SOUTH MIDDLESEX DIVISION.**—A Middlesex Division will be held at St. John's on Wednesday, January 21st, at 8.15 p.m. A discussion on scarlet fever from a public health point of view will be opened by Dr. H. A. Gunther.

**METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.**—A meeting of the South-West Essex Division will be held at Walthamstow Hospital, Orford Road, on Tuesday, January 6th, at 5.30 p.m. precisely. Agenda: Correspondence; discuss holding an annual dinner of the Division; communication from Medical Secretary regarding the report of the Ophthalmic Committee on the treatment of cases of refraction in insured patients; preliminary notice of a special meeting of the Division to consider the Memorandum of Evidence for presentation to the Royal Commission on National Health Insurance (see page 1). At 4.15 p.m. Mr. A. Tudor Edwards, F.R.C.S., surgeon to Westminster Hospital and Walthamstow Hospital, will read a paper on the significance of signs and symptoms in diseases of the genito-urinary tract. Tea will be served at 3.15.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, January 21st, at 9 p.m., to consider the draft evidence to be submitted to the Royal Commission on National Health Insurance. In preparation for this meeting members and non-members of the Association are requested to attend an important meeting of all practitioners in Middlesex to be held at the Portman Rooms, Baker Street, W.1, on Sunday, January 18th, at 3 p.m., when Dr. H. B. Brackenbury will speak.

**MANCHESTER BRANCH: CHESTERFIELD DIVISION.**—A meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, January 9th, when a discussion on the use of insulin in general practice will be opened by Dr. A. Court.

**NORTHERN COUNTIES OF SCOTLAND BRANCH.**—A meeting of the Northern Counties of Scotland Branch will be held at Inverness on Friday, January 16th, when Professor A. W. Mackintosh will deliver a British Medical Association lecture entitled "Neurological findings."

In the morning the Collier Cup will be competed for at Frilford Heath, and in the afternoon Mr. Roberts will read a paper on modern chest surgery.**

## Insurance.

### MEETINGS TO DISCUSS MEMORANDUM OF EVIDENCE TO THE ROYAL COMMISSION.

The following meetings have been arranged to consider the draft Memorandum of Evidence to be submitted by the British Medical Association to the Royal Commission on National Health Insurance, which is published in the SUPPLEMENT this week.

#### Middlesex.

A meeting of all the medical practitioners in the county of Middlesex will be held under the auspices of the Divisions of the British Medical Association and of the Panel Committee on Sunday, January 18th, at 3 p.m., in the Portman Rooms, 59, Baker Street, for the purpose of considering the draft Memorandum of Evidence to be presented to the Royal Commission on National Health Insurance. Dr. H. B. Brackenbury will explain the memorandum, and discussion will follow. The meeting is intended to assist the discussion which will take place at the meetings of the Divisions which are to be held later. As the matters to be discussed are of vital importance to the whole profession a large attendance is desired. The Portman Rooms are three minutes' walk from Baker Street Station.

#### Marylebone Division.

At 11, Chandos Street, W.1, on Wednesday, January 14th, at 8 p.m.

#### Willisden Division.

At Willisden General Hospital, Harlesden Road, N.W., on Wednesday, January 21st, at 9 p.m.

#### Sheffield Division.

In conjunction with the Sheffield Local Medical and Panel Committees, at the Church House, St. James Street, Sheffield, on Friday, January 16th, at 8.30 p.m.

#### North-East Essex Division.

At the Red Lion Hotel, Colchester, on Friday, January 9th, at 3 p.m.

#### West Bromwich Division.

At the offices of the Southwick Insurance Committee, 1, South Street, Southwick, on Tuesday, January 6th, at 3 p.m.

#### Guildford Division.

On Thursday, January 15th. Time and place of meeting to be announced later.

As pointed out in the leading article published in the JOURNAL at page 30, it is of great importance that every medical practitioner, whether serving under the Insurance Act or not, and whether a member of the British Medical Association or not, should attend the meeting in his district.

## Correspondence.

### Cheshire and Flintshire Scheme for a Pathological Service for Insured Persons.

Sir,—A meeting of the Joint Committee responsible for the administration of the above scheme, recently held, has, *inter alia*, considered the points to which attention was directed by the article appearing in your issue of October 11th, 1924 (SUPPLEMENT, p. 133), and the Joint Committee desires me to submit the following observations relative thereto.

In reconsidering the question of the application of Clause 10(2) of the Terms of Service of Insurance Practitioners in its relation to the scheme in the light of information which was obtained at an interview with the Ministry of Health and otherwise, the Joint Committee felt some obscurity on this point did arise in its circular of September 26th.

The Joint Committee, therefore, has decided to withdraw the paragraphs referring to this particular question in the circular, and instead to substitute the following, which are more clearly definitive of the relative positions of practitioner, patient, and Joint Committee, namely:

Paragraph 12.—"It is considered that Clause 10(2) of the Terms of Service of Insurance Practitioners, Medical Benefit Regulations, 1924, will not apply to the acceptance by the practitioner for transmission to the laboratory of any fee paid in respect of the service rendered by the laboratory to his insured patient in this connection."

Paragraph 13.—"The Committee accepts no responsibility for the payment of fees, which will be a matter of arrangement between the insured person and the Pathologist; therefore, should be sent direct to (either by the insured person or by the insured person, who will ordinarily be responsible to the Pathological Department for the payment of the fees."

A later communication from the Ministry of Health is regarded as indicating that the arrangement now arrived at clears up the points in question.

Insurance practitioners are now assured that under the new arrangements Clause 10(2) of the Terms of Service of Insurance Practitioners, Medical Benefit Regulations, 1924, will not apply.

With respect to the second point raised in your article, the Joint Committee did not intend when requiring reports from the Pathological Department that such reports should contain any information as to the name and address of the person in respect of whom the examination had been made, but to avoid even the remotest possibility of information of a private and confidential nature in respect of any patient being divulged, either inadvertently or otherwise, it has readily accepted and adopted the following suggestion, namely:

That the pathologist shall at each meeting of the Joint Committee make a brief report, to contain nothing more than the number and type of examinations which have been made, the number of autogenous vaccines which have been prepared, and the particular places or districts from which material has been received, concluding with a statement of the amount of fees received in respect of such examinations.

The Joint Committee desires particularly to state that reports on specimens, etc., will be treated as private and confidential documents by the Pathological Department, and will not be open to either official or unofficial investigation.

The Joint Committee further has the authority of the Board of the Infirmary to give the assurance that the pathologist will be properly remunerated in accordance with the hospital policy of the British Medical Association.

In conclusion, it is desired to state that the benefits of the scheme have now been extended to the dependants, widows, and orphans of insured persons, and that from the short experience of its operation it promises to meet a very real need.—I am, etc.,

Chesler, Dec. 20th, 1924.

F. FREDERICK WEST,  
Honorary Secretary.

•• We are very glad to note that the points to which attention was drawn in the SUPPLEMENT of October 11th, 1924, have been acknowledged and met in a satisfactory way by the Joint Committee.

## VACANCIES.

ADLAIDE UNIVERSITY.—Marks Lectureship in Applied Physiology and Sheridan Fellowship. Salary £750 per annum.

BERMONSEY BOROUGH.—Assistant Medical Officer (female) for Maternity and Child Welfare. Salary at the rate of £600 per annum.

*President:* W. MARDON BEAUMONT, M.R.O.S. (Bath).

*Vice-Presidents:* R. WALLACE HENRY, M.D. (Leicester); A. W. OMMOND, C.B.E., F.R.C.S. (London); C. H. WALKER, F.R.C.S. (Bristol).

*Honorary Secretaries:* R. COLLEY, M.B., D.O.M.S., 30, The Circus, Bath; P. G. DOYNE, M.B., F.R.C.S., 8, Harley Street, London, W.1.

**ORTHOPAEDICS.**

(One day being combined with Surgery.)

*President:* Professor E. W. HEY GROVES, M.S., F.R.C.S. (Bristol).

*Vice-Presidents:* NAUGHTON DUNN, M.B., Ch.B. (Birmingham); G. L. GIRDLESTONE, M.B., F.R.C.S. (Oxford); E. MUIRHEAD LITTLE, F.R.C.S. (London).

*Honorary Secretaries:* T. TWISTINGTON HIGGINS, O.B.E., F.R.C.S., 27, Harley Street, London, W.1; J. S. LEVIS, M.C., M.B., 20, Gay Street, Bath.

**PUBLIC MEDICINE.**

*President:* T. EUSTACE HILL, O.B.E., M.B., D.Hy. (Durham).

*Vice-Presidents:* T. W. NAYLOR BARLOW, C.B.E., M.R.O.S., L.R.C.P. (Walsley); J. F. BLACKETT, M.D. (Bath); W. A. BREND, M.D. (London); S. NOY SCOTT, M.R.C.S., L.R.C.P. (Plymouth).

*Honorary Secretaries:* A. NEVILLE COX, M.D., M.R.C.P., 21, Cornwall Gardens, Preston Park, Brighton; R. E. THOMAS, M.D., 11, Darlington Place, Bath.

**The following Section will meet on One Day.****MEDICAL SOCIOLOGY.**

*President:* CHARLES E. S. FLEMING, M.R.C.S., L.R.C.P. (Bradford-on-Avon).

*Vice-Presidents:* J. W. BONE, M.B., C.M. (Luton); WILFRED BUCKLEY, C.B.E. (London); G. P. MALE, M.R.C.V.S. (Reading); E. A. STARLING, M.B., M.Ch. (Tunbridge Wells).

*Honorary Secretaries:* C. J. BUCHAN, M.B., 326, Brownhill Road, Catford, London, S.E.6; C. A. MARSH, M.D., 20, Victoria Buildings, Bath.

The Honorary Local General Secretary is Mr. W. G. MUMFORD, O.B.E., F.R.C.S. (British Medical Association Committee Rooms, Assembly Rooms, Bath); and the Honorary Assistant Secretary is Dr. R. G. GORDON.

**British Medical Association.****CURRENT NOTES.****National Health Insurance and Public Health.**

At a recent meeting of the West Somerset Branch of the British Medical Association Dr. W. G. Savage, county medical officer, opened a discussion on the relationship between a national insurance scheme and the public health with a valuable paper, in which he drew attention to the various ways in which the connexion between the two might be made closer and more effective. The necessity for this, and some methods for bringing it about, are stated in the draft Memorandum of Evidence proposed to be given before the Royal Commission (SUPPLEMENT, January 3rd, 1925, pp. 1-9), and it is highly important that this part of the whole subject should be kept in view at the meetings of the profession now being held to consider the Memorandum. In his paper Dr. Savage points out that an insurance scheme necessarily breaks down the economic antagonism between preventive and curative medicine which has in some degree previously existed, and that the public health work done by insurance practitioners has been extensive and valuable. Though Dr. Savage has some objections to the form of record which has to be kept by such practitioners, it has to be borne in mind that this form was drawn up by an experienced and representative committee, which gave full attention to its possible statistical and research purposes, though it was recognized that its prime use was clinical. To the present lamentable neglect to use these records—even such of them as are returned to the authorities when those to whom they refer have died or ceased insurance—Dr. Savage draws serious attention, and his suggestion that the medical officers of the local authority (and not only the officers of the Ministry of Health, as at present) might be afforded opportunity of utilizing them is worthy of favourable consideration. He points out, too, that the possibility of making special investigations by means of particular records in certain localities as to the incidence of diseases in the area has been very little used, and, indeed, seems to be very imperfectly realized. Here again it is obviously desirable that the local health authority and its medical officer should be brought into close and organic connexion with a national health insurance scheme. Some of the wider public health activities assigned to or contemplated for Insurance Committees by the original Act of 1911 have never been carried out, and experience compels the recognition that these are, in fact, impossible; but this makes it all the more necessary that other means should be sought for utilizing the great opportunities which a health insurance scheme offers for furthering the public health by affording information in accordance with which preventive measures may be taken, and interesting in them a large body of practitioners who must necessarily be actively associated with such measures. Dr. Savage has done good service by his paper, and it is to be hoped that other medical officers of health will follow his example.

**Certification Risks.**

The North of England Branch of the British Medical Association has done a very useful piece of work in issuing to all its members a "Memorandum on Certificates, Notifications, Reports, etc." The memorandum quotes the Warning Notice of the General Medical Council as regards certificates. Then follow some instances of cases of alleged wrongful or careless certification which have come before the General Medical Council in the past two or three years; and the memorandum ends with the following paragraph:

"It is necessary for medical practitioners to recognize that, if regulations under the National Health Insurance scheme cause inconvenience or appear to press hardly upon the insured person, this does not absolve the medical man from the responsibility which attaches to appending his signature to a certificate. A doctor attaching his signature and the qualifications which make it valid under the Medical Act vouches for the accuracy of the statements made in the certificate, and must accept any consequences that flow therefrom."

Other Branches of the Association might well copy the example of the North of England Branch and remind their

members from time to time of the responsibilities which doctors undertake in signing certificates and reports, and of the penalties which may be entailed by carelessness or mistaken kindness of heart.

#### Examination of Immigrants to the United States.

Owing to the severity of the conditions governing the entry of immigrants to the United States, medical practitioners in this country are now being confronted with various forms of certificates of fitness. Some of these are drawn up by shipping companies in their own defence, and as they are not unduly exhaustive the Medico-Political Committee of the British Medical Association has taken no exception to them, but has recommended Divisions that the fee for filling them up should be not less than 10s. 6d. There is, however, one official form of certificate to which the Committee takes very great exception on account of the technical knowledge of a number of diseases extremely uncommon in this country which would be necessary if the certificate were to be conscientiously dealt with. It has to be borne in mind that the signing of these certificates involves a very serious responsibility, because if it is found that an intending immigrant shows signs of any of these diseases on landing a heavy fine is inflicted upon the shipping company which has brought him over, the unfortunate ship surgeon gets into trouble, and the immigrant has to be taken back at the expense of the shipping company. The very serious view which the General Medical Council now takes of anything which may savour of laxity in certification must also always be remembered. The Medico-Political Committee considered that it was altogether too much to expect of the general practitioner with no tropical experience that he should certify that a given individual was not suffering from any of the following diseases: actinomycosis, blastomycosis, framboesia, mycetozoa, Oriental sore, filariasis, amoebiasis, schistosomiasis, or other dangerous conditions caused by animal parasites. The Committee considered that it would be fully justified in recommending the Council of the Association to advise its members to have nothing to do with this certificate, no matter what fee should be offered, and the Council, without hesitation, adopted the Committee's recommendation. Members are therefore advised that if they should be confronted with one of these forms they should refuse to fill it up under any conditions.

#### Correction of Draft Evidence for Royal Commission on Insurance.

By a printer's error a line has been dropped out of paragraph 10 of the draft Memorandum of Evidence proposed to be given by the British Medical Association to the Royal Commission on National Health Insurance. The following correction should be made in all copies of the SUPPLEMENT of January 3rd, 1925:

Page 2, col. 1, para. 10, last line but one, after the word "without" insert "any income limit and (b) non-manual workers with an income"

#### Middlemore Prize, 1925.

The Middlemore Prize was founded by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association might from time to time select in any department of ophthalmic medicine or surgery. For many years the prize has been awarded to the author of the best essay received in connexion with a specific subject, but it has been decided on this occasion to deal with the award of the prize on a broader basis. The Council will accordingly award the prize in the year 1925 to that person who is adjudged to have submitted to the Association the best contribution on any ophthalmological subject, whether previously published or not, provided that the contribution shall not have been published or prepared more than three years prior to the date on which applications are receivable in competition for the prize. The prize will take the form of an illuminated certificate and a cheque for £50. Contributions in competition for the prize must reach the Medical Secretary, British Medical Association, 429, Strand, W.C.2, on or before

Monday, February 2nd, 1925. The contributions will be judged by examiners appointed by the Association, and the decision of the Council will be final.

## Association Notices.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, January 22nd, when Dr. K. D. Wilkinson will speak on cardiac irregularity.

**BORDER COUNTIES BRANCH: ENGLISH DIVISION.**—A meeting of the English Division and Cumberland Panel Committee will be held in the County Hotel, Carlisle, on January 13th, at 3.30 p.m., for consideration of the evidence to be placed before the Royal Commission on National Health Insurance. The meeting will be addressed by the Medical Secretary, Dr. Alfred Cox, and those attending should take with them the BRITISH MEDICAL JOURNAL SUPPLEMENT of January 3rd.

**SOUTH MIDLAND BRANCH: BUCKINGHAMSHIRE DIVISION.**—A special joint meeting of the Bucks panel practitioners and the local members of the British Medical Association will be held at the Crown Hotel, Aylesbury, on Friday, January 16th, at 5 p.m., to discuss the Memorandum of Evidence to be submitted to the Royal Commission. All practitioners in the area are invited. Any resolutions from this meeting will go to the Insurance Acts Committee and later to a Conference of Representatives in London. Therefore it is essential that all suggestions should be submitted as soon as possible. It is desired to emphasize before the Royal Commission the special difficulties under which country practitioners work, and the Secretary (Dr. T. Perrin, 10, Temple Square, Aylesbury) will be glad to receive any suggestions from rural practitioners.

**EASTERN COUNTIES DIVISION.**—A special Counties Division will be held in Medical and Panel Committees of the Newtown St. Boswells, on Wednesday, January 15th, at 5 p.m., to consider the draft evidence proposed to be put before the Royal Commission on National Health Insurance on behalf of the British Medical Association.

**ESSEX BRANCH: NORTH-EAST ESSEX DIVISION.**—A meeting of the Division, to which all medical practitioners are invited, will be held at the Red Lion Hotel, Colchester, to-day (Friday, January 9th), at 3 p.m., to consider the Memorandum of Evidence which is to be submitted in the name of the Division to the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. Alfred Cox, Medical Secretary, who will also be pleased to answer questions.

**GLOUCESTERSHIRE BRANCH.**—At the meeting of the Gloucestershire Branch to be held on Saturday, January 10th, Sir Humphry Rolleston, Bt., K.C.B., President of the Royal College of Physicians of London, will give an address.

**KENT BRANCH: BROMLEY DIVISION.**—A meeting of all medical practitioners in the Division will be held at the United Services Club, London Road, Bromley, on Friday, January 16th, at 8.30 p.m., to consider the draft Memorandum of Evidence which is to be submitted to the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. G. C. Anderson, Deputy Medical Secretary, who will also answer any questions.

**LANCASHIRE AND CHESHIRE BRANCH: MID-CHESHIRE DIVISION.**—A British Medical Association lecture will be given on Friday, January 16th, at 8.45 p.m., in the Board Room of the Altrincham General Hospital, by Dr. S. A. Kinnier Wilson (London) on Neuritis and Neurasthenia. Members of neighbouring Divisions are heartily welcome.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—The next meeting of the City Division will be held at the Metropolitan Hospital on Tuesday, January 13th, at 9.15 p.m., when Mr. McAdam Eccles, M.S.Lond., F.R.C.S.Eng., will read a paper entitled "Lessons learnt from the chief skiagrams taken in my 'firm's' work during 1924 at St. Bartholomew's Hospital," illustrated by lantern slides. Meetings of the medical profession in the area of the City Division will be held at Shoreditch and Islington. The Islington meeting is to be held in the Islington Town Hall on Tuesday, January 20th, at 9.15 p.m. Dr. G. C. Anderson will open the discussion on the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance. The date and place of the Shoreditch meeting will be announced in next week's SUPPLEMENT.

**METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.**—A meeting of the Kensington Division will be held at the Kensington Town Hall at 3.30 p.m. on Friday, January 23rd, to discuss the evidence it is proposed to place before the Royal Commission on National Health Insurance. It is hoped that all medical men in the Divisional area, whether members of the Association or not, will attend and express their views, as the matters under discussion will affect all practitioners in whatever class of work they are engaged.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—It is proposed to hold a meeting of all medical practitioners residing in Lewisham on Wednesday, January 14th, at 8.45 p.m. at the New Hall, St. Laurence Church, Bramley Road, Catford, S.E.6, to

DORSET AND WEST HANTS BRANCH: BOURNEMOUTH DIVISION.  
A MEETING OF THE Bournemouth Division was held on December 17th,  
1924, in St. Peter's Church, Bournemouth. The Rev. Canon G. W. G. gave his report  
of the work done during the year. He said that the Annual Report delivered by Dr.  
Bernard Myers, Secretary of the Division, was very important that every care should be taken of nervous children.

as some of the world's greatest men and women were of the neurotic type. Remarking that a nervous child could be detected by the trained eye during the first few days of life, the lecturer described the characteristics of the nervous patient during infancy, school age, and adult life. He quoted statistics from a London clinic showing the percentage of the various signs and symptoms in a large number of cases. As regards treatment, he said that the environment of the child was of the greatest importance, and of drugs bromide was of most value.

## KENYA BRANCH.

A meeting of the Kenya Branch was held at Nairobi on June 11th, 1924. Dr. A. J. JEX-BLAKE, the President, who was in the chair, read a paper on euccephalitis lethargica, and, in the absence of Mr. H. H. V. Welch, described two cases of the disease which had occurred at the European Hospital, Nairobi. Dr. Jex-Blake was cordially thanked for his interesting paper.

Dr. F. J. C. Johnstone was elected honorary secretary in succession to Dr. C. J. Wilson, who had resigned through pressure of other work. On the motion of Dr. BUNKITT, seconded by the CHAIRMAN, a hearty vote of thanks was accorded to Dr. Wilson for the very efficient manner in which he had carried out the duties of honorary secretary.

At the meeting held on July 9th, Dr. G. V. ALLEN read a paper on the diagnosis of amoebiasis, illustrated by blackboard diagrams, which was followed by a demonstration of microscopical specimens. A discussion followed, and a vote of thanks was accorded to Dr. Allen for his paper.

Dr. R. W. BUCKITT demonstrated a case of an eye in an Indian child from whom the other eye had been removed three months before.

The Branch met again on August 13th, under the chairmanship of the President, Dr. A. J. JEX-BLAKE. A paper on artificial feeding and disorders of infants read by Dr. G. V. W. ASCHERSON gave rise to considerable discussion, in which the majority of those present took part. A hearty vote of thanks was accorded to Dr. Anderson for his paper.

At the meeting of the Branch on October 8th Dr. R. W. BUCKITT, Vice-President, who took the chair, read a paper on the modern treatment of fevers, with suggestions as to the treatment of animals. A general discussion ensued, and Dr. Buckitt was thanked for his interesting and original paper.

## METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

A MEETING of the Lewisham Division was held on December 16th, 1924, at the South-Eastern Children's Hospital, Sydenham, with Dr. F. A. BEATTIE in the chair. On the motion of Dr. CHANLEY, seconded by Dr. E. C. ARNOLD, a resolution was carried unanimously expressing strong disapproval of the Hospital Saving Association scheme.

Dr. H. B. GLADSTONE showed diet and weight charts of marasmic children. Dr. SHUTTLEWORTH showed x-ray plates of fracture of the right hip in a lady of 63 years. Dr. CHANLEY described a case of suppurative cystic non-malignant tumour of the breast. Dr. BARNES described a case of "acute abdomen" which showed on operation thousands of glands studded over the intestines—a case of Hodgkin's disease. Dr. BARNES showed a case of osteitis deformans, in which there was great enlargement of the head, curving of the bones of the left arm, and bow-legs. The patient had complained of pain in the lumbar region for four years. Dr. CHANLEY described the case of a child aged 2½ years thought to be suffering from encephalitis lethargica. Dr. BARNES described the case of a soldier who had haemolytic jaundice for ten days in July, 1918, since when he had eight or nine attacks. The liver was enlarged. The blood count showed reds 2,248,000 and whites 2,650 per cubic millimetre; there were no nucleated red cells; bile was present in the urine.

The members were afterwards shown over the new out-patient department of the hospital.

## METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.

AN ordinary meeting of the South Middlesex Division was held at St. John's Hospital, Twickenham, on December 11th, 1924, when Dr. G. S. EWEN was in the chair.

Dr. Provis read a paper on ante-natal care. He considered that many patients who attended the clinics might quite well be treated by their own medical practitioner. It was important to take the history and make a thorough examination of the mother. The urine should be tested at least one month after attending the clinic, and re-examined from time to time. The breasts also should be examined and treated if necessary, the pelvis examined and measured, and the presentation diagnosed. The question of turning the child might be considered in breech cases where it could easily be done, but as it was apt to return to its former position its value was doubtful. It was not considered advisable to make internal examinations as a routine, except in doubtful cases of those of primiparae. The diagonal conjugate should then be measured and the size of the outlet estimated. In cases with a history of miscarriage a Wassermann test should be made and treatment given where needed. When positive, the blood of the infant must be tested on several occasions after birth. In cases of gonorrhoea active treatment was necessary. Dr. Provis used methyl violet and often swabbed out with 20 per cent. bile salts, which seemed to have beneficial effect.

Dr. Provis stated, in reply to a question by Dr. Yoxce, that the woman should attend the ante-natal clinic at the sixth month.

Dr. PENROU considered it important to estimate the ratio between the size of the head and the pelvic outlet; he also discussed castor oil and quinine treatment, and the use of pituitrin. Dr. RUDNOCK-WEST discussed how often it was necessary to hold ante-natal clinics. Dr. DUNSTON considered that about eight new cases would be seen on each occasion, representing approximately 400 new cases per annum. Dr. COOK thought that sufficient stress had not been laid upon the examination of the urine in ante-natal cases; he received three or four cases of eclampsia each year which might have been treated much earlier. He obtained excellent results in gonorrhoea cases by diathermy.

## SOUTH-WESTERN BRANCH: EXETER DIVISION.

THE annual meeting of the Exeter Division was held in the library of the Royal Devon and Exeter Hospital on October 17th, 1924, under the presidency of Dr. R. V. SOLLY, Chairman.

Dr. Solly vacated the chair to Dr. VINCENT SMITH, and the following officers were elected for 1924-25:

Vice-Chairman, Dr. J. A. W. Pereira Gray. Representative in Representative Body, Dr. F. A. Roper. Secretary, Mr. Norman Lock.

The Representative, Dr. ROPER, then reported on the proceedings at the Representative Meeting at Bradford, and commented especially on medical evidence in courts of law, fees in cases of street accidents and for ambulance lectures, lunacy certificates, medical defence, hospitals.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH: NORTH GLAMORGAN AND BRECKNOCK DIVISION.

To give the members an opportunity of inspecting the new hospital, Mountain Ash, the meeting of the North Glamorgan and Brecknock Division of the British Medical Association was held at the institution on December 16th, 1924.

The Secretary, Dr. ARTHUR T. JONES, J.P., gave an interesting account of the Cottage Hospital and of the work done there during its thirty years' existence. It was opened in 1895, which happened to be the year he went to Mountain Ash. Twenty-one patients were admitted during this first year, and an average of 32 patients per annum were admitted for the following eight years, up to 1904. In 1905, the hospital was enlarged by the building of an additional ward of five beds, making a total of twelve beds. For the next four years, an average of 84 patients were admitted annually. In 1908, two more wards were added, together with a new and commodious operating theatre. The total number of beds was brought up to 17, and an average number of 107 patients had annually been admitted, the largest number being 130 in 1910, and the smallest, 79, in 1918. The total number of patients treated at the Cottage Hospital was 2,337. The population of the urban district area in 1896 was 25,650. The population of the whole area to-day was over 46,000, and that of Mountain Ash and Penrhiwceder—excluding Abercynon and Ynysydwyl—was 30,055. The increase in population had necessitated a larger building, and the scheme of a new hospital had fructified in the erection of a fine and commodious building on modern lines, and equipped with the most modern surgical appliances.

The members were subsequently escorted around the building by Miss Morgan (matron), after which they were entertained to tea by Dr. and Mrs. Arthur Jones. A hearty vote of thanks was accorded to Dr. and Mrs. Jones for their hospitality, to Miss Morgan and her staff for carrying out the arrangements, and also to the board of managers for allowing the Division to meet at the hospital.

## SOUTH WALES AND MONMOUTHSHIRE BRANCH: SOUTH-WEST WALES DIVISION.

At the meeting of the South-West Wales Division at the Carmarthenshire Infirmary on November 26th, 1924, Mr. HENRY WADE, C.M.G., D.S.O., lecturer in clinical surgery in the University of Edinburgh, and surgeon to the Edinburgh Royal Infirmary, gave an interesting address on the differential diagnosis of cases simulating appendicitis, which was highly appreciated by all present. After the lecture Mr. Wade gave a lantern demonstration of pyelograms and x-ray plates illustrating kidney and ureteral conditions which simulated appendicitis. At the close of the meeting a hearty vote of thanks was, on the motion of the Chairman, Dr. J. PHILLIPS, seconded by Dr. PARRY, accorded to Mr. Wade for his interesting lecture.

A further meeting of the Division was held on December 19th. A subcommittee was appointed to arrange for a social meeting in the summer at Llanelly, at which the Branch would be entertained by the South-West Wales Division.

Drs. R. Jones, Evans (Tumble), and A. H. D. Smith, were elected members of the new Welsh Contract Practice Subcommittee.

Drs. T. R. Davies and Dr. Oscar Williams (Llanelly) were elected Representative and Deputy Representative respectively in the Representative Body.

## YORKSHIRE BRANCH: SCARBOROUGH DIVISION.

THE annual meeting of the Scarborough Division was held on December 16th, 1924, at the Royal Hotel. The following office-bearers were appointed for 1925:

Chairman, Dr. Forman. Vice-Chairman, Dr. Fox Linton. Honorary Secretary, Dr. Chapman. Representative in Representative Body, Dr. Candler-Hope.

The annual dinner of the Division was held the same evening at the Royal Hotel, when the principal guest was the Mayor of Scarborough.

## OPHTHALMIC BENEFIT FOR INSURED PERSONS.

BY

N. BISHOP HARMAN, M.A., M.B.CANTAB., F.R.C.S.ENG.,  
SENIOR OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL, ETC.

AMONG "additional benefits" provided through the National Health Insurance Acts dental and ophthalmic are easily first in demand and in value to insured persons. Dental benefit is imperative if preventive medicine is to be developed, for untreated dental disease is the forerunner of many and grave general disorders, which may be prevented with comparative ease, but are cured, if cured at all, with great difficulty. Ophthalmic benefit appeals greatly to the insured person, for the symptoms of eye-strain are most disturbing, and are more frequent with the increasing complexity of modern life.

A few approved societies have provided ophthalmic benefit by entering into arrangements with qualified and registered medical practitioners, and according to my information the arrangements have proved thoroughly satisfactory to the insured persons, of value to the panel practitioners who are responsible for the treatment of those persons, and economically practicable.

Other approved societies have entered into arrangements which are open to serious criticism and are certain to lead to grave danger to the insured persons. These societies have arranged for the provision of spectacles by opticians and without the necessary preliminary examination by a qualified doctor. The arrangement, it is alleged, is cheap. But it should be remembered that cheap methods in dealing with human beings usually prove costly in the long run. It is sure to prove so in this regard, for reasons that are easy to set out. There are other reasons affecting general economics which should be taken into account.

1. *Serious Organic Disease.*

Five per cent. of eye cases show serious organic disease. These cases are scattered throughout the whole, and commonly give no warning of their nature. Often the complaint is only made of dimness of vision, and a request is made for glasses to see with. These cases commonly have some error of refraction the correction of which materially improves vision, so that the optician may consider that he has done all that is needed by giving glasses; whereas the real root of the trouble has remained undiscovered. There is no doubt that opticians are beginning to be fearful of these risks, for one often gets cases which have been recommended to go to hospital or to an eye surgeon; some of these are cases of real defect and danger, others show no such defect or danger, and the appearance of these latter cases shows that the optician cannot, from the absence of sufficiently wide training, make a satisfactory distinction.

2. *Myopia and Industrial Conditions.*

Of the 95 per cent. of cases it should be remarked that these are by no means straightforward "optical" cases in which eyes as optical instruments independent of a human body may be dealt with by an optician with mechanical measuring instruments. Of these 95 per cent. some 10 per cent. are myopes of more than low degrees. A couple of years ago I examined serially 7,000 private case papers of my own; of these 480 were between the ages of 20 and 60 years, with three or more dioptres of error. Of these cases no less than 26 per cent. showed serious conditions of eye-strain or failure which required much more than "optical" treatment; and amongst those engaged in close eyework no less than 53 per cent. had breakdowns. The figures of that investigation were published widely in the United Kingdom and in the United States of America, and so far there has been no challenge to the deductions drawn therefrom. As a matter of fact, they have been so far accepted that material decisions have been based upon them. It shows what an immense amount of medical attention is involved in these cases, and with that a wide knowledge of life and of everyday work if any really useful benefit is to accrue to these people.

3. *Eye-strain in Young Adults.*

One is amazed at the number of young people who come complaining of symptoms of eye-strain or of headache and in whom there are found only very small errors of refraction—such small errors as may be found in a large proportion of the population, or even the majority of the people, and without causing any trouble even in these who work at benches or desks. To the optician these are cases for glasses. To the doctor who does ophthalmic practice they are cases for much wider investigation. He wants to know why there is this supersensitiveness, and he is often able to discover probable causes of trouble and

indicate to the private practitioner what is the line of treatment that is best likely to benefit the patient. Such treatment is by no means confined to the ordering of glasses or drugs; it enters into the details of the patient's life, and without that there is certain to be a failure of effect.

It may be said that much of this advice might be given by opticians of experience. In practice this is not so. Advice of this kind can only be given on the basis of a wide experience, such as is obtained by the doctor in an educational experience of men and of health problems which the medical curriculum is designed to afford, and which it undoubtedly does afford. No training in a narrow groove can accomplish this. So that if it should come about that a material part of medical treatment and consultation were given into the hands of men trained in such a narrow groove it is inevitable that a great part of the "medical benefit" would be lost. The provision would be penny wise and pound foolish.

4. *Signs of Wear and Tear.*

There has to be considered the special problem of the adults. In these persons the beginning of wear and tear is often to be seen most easily and often as a first indication by difficulty in the eyes. The changes in the cornea, in the iris and the reaction of the pupil, changes in the lens, vitreous, and above all in the state of the vessels of the retina, are so well known as an indication of ageing of the tissues and the disabilities that arise therefrom that these examinations are a necessary part of every medical examination which is designed to discover the true state of the body of the patient. With a properly designed medical benefit covering ophthalmic examination all this information would be at the disposal of the private doctor of the patient. The advantage would be immense, and probably the saving that could be effected by the early discovery of indications of general wear and tear would be so great as to balance any cost of this additional benefit. It is not to be expected that this advantage could be obtained by the use of opticians, unless, indeed, it were proposed to subject these persons to such a wide and lengthy curriculum that it would be to all intents and purposes coextensive with the medical curriculum, in which case it would be more advantageous to put them through the medical course right away.

5. *Covering.*

The provision of additional medical benefit must have safeguards, so that the call upon the benefit shall be given to those only to whom it will be of advantage, and to secure that it shall not be given unnecessarily, and therefore wastefully. That means that it must be given under the order of the private panel practitioner, possibly with some mechanism of appeal in case of disagreement as to the necessity of the provision of the benefit. If the benefit is obtained through doctors qualified in eye work no ethical question arises; it is the regular procedure. If it were proposed to give it through opticians a serious ethical matter would immediately arise. For a panel practitioner to advise a patient to obtain part of his medical treatment through the agency of a person not on the *Medical Register* would be "covering" in the terms understood by the General Medical Council. The panel practitioner so doing would be liable to proceedings being taken against him. Consequently, panel practitioners would not advise their patients to go to opticians, so that the benefit provided would be unobtainable through the proper channels. It might be null and void.

It may be said that general practitioners have in the past advised their patients to go to opticians for sight-testing, and that they do so now. There is evidence that this practice is declining for the very reasons set out, and also because there are now many more doctors engaged in eye work, and who see patients for fees which the industrial classes can afford.

6. *Opticians.*

It may be said that only those opticians who are well equipped for their work would be recognized. That would be no solution to the difficulty. Those recognized may or may not be pleased with the recognition, according to the terms in which it is given. If recognition should have coupled therewith prohibition to advertise (as on the experience of the *Dentists Register* may be held likely) they would not be pleased. For the rest of their sort who were not recognized would be free to advertise as they do now. Further, it is likely that any attempt to recognize some and not all of these persons would bring the rest of them—that is, the majority of the sight-testing fraternity—into the field with vehement protestations against the injustice of the procedure. There are already more than a few "bills" suggested in the interests of the several sections of sight-testers.

7. *The Education of the Public.*

There is one argument that appeals very strongly to me, and it is one that I am inclined to think will appeal most strongly to the persons most affected—that is, the insured. For eighteen

<sup>1</sup> Harman, *The Consequences of Myopia as an Industrial Disease of the Kingdom*, Transactions of the Ophthalmological Society of the United Kingdom, 1922, p. 20.

years one great department of State has rigorously set its face against sight-testing by any other than properly trained and qualified doctors. The Board of Education has made it plain that in dealing with children the best possible is the only admissible, and that there is no second best. One generation of children have learned this, and now they are the fathers and mothers, and they see their children treated in this same proper fashion. Is it to be expected for one moment that these parents will be content if they are fobbed off with second or third best, an optician instead of a properly trained eye doctor?

I am inclined to think that if the authorities concerned attempted to set up such an inferior grade of optical benefit there would be raised such a volume of protest that they will wish they had never suggested such an idea. The matter would no longer be a matter of the best way of doing medical work, or a question of medical ethics; it would become a matter of politics; and the cry would be raised that the authorities propose to give medical treatment for the masses which they as the classes would not be content with themselves.

It may be said that many of the industrial classes do now betake themselves to these same sight-testing opticians. True. But what a man will do of his own free choice he will not tolerate when it is provided for him by a Government authority. At present he has a choice between the cost of loss of time involved in attending a hospital or the cost of paying an optician; he takes one or the other course, as is most convenient to him, and he knows he does it at his own risk, so far as the optician is concerned. It will be far otherwise with a Government prescription of an optician for sight-testing. I can see any such suggestion becoming a violent political controversy, and I am inclined to think that in that contest the usual forms of "stunt" would be employed to make any action by Government in recognizing or employing optician sight-testers for insured persons look exceedingly bad.

### 8. Long Views.

It is necessary on occasions to take long views. A procedure which may conceivably suggest a temporary advantage will be found on looking forward to lead to an increasing disadvantage. The number of doctors who do eye work has increased considerably in recent years, particularly since the medical treatment of school children was organized; but the increase has been far less than is warranted by the necessities of the population. The reason for this failure of adequate provision lies in the exploiting of the field by the advertising sight-testing optician. Fathers hesitate to make a heavy expenditure on the training of their sons for such work, and young doctors whose bent is for this work turn to other fields when they see the odds so much against them. The same was seen in the dental field, and the State had to take measures to protect itself. The rapid exploitation of dental work by hosts of untrained advertising tooth-drawers inhibited the provision of qualified dental surgeons so seriously that the State stepped in, sorted out the untrained into the passable and the bad, put the passable on an expanded *Dentists Register*, and thereon determined that there should be no more dental practice except by the registered, and no further entry to the *Dentists Register* except to the properly trained and qualified. It is now certain that at no distant date there will be a full supply of trained and competent dental practitioners.

A recognition of sight-testing opticians, temporary or otherwise, will certainly inhibit the provision of doctors who do eye work. Further, should sight-testing opticians be recognized, they could never be incorporated in any sort of medical register. The die will be cast for weal or woe.

It cannot be argued that the midwives' register is a comparable action by the Legislature. Parturition is a physiological act. Abnormalities may be discovered beforehand, and the signs of danger at or after childbirth are so distinctive that failure of a midwife to summon a doctor to such cases is an offence, and leads to penal action. Further, it is likely that at no distant date the midwife will be eliminated, from economic and domestic reasons. There is increasing tendency in civilized countries for the lying-in to be arranged in a nursing home. This practice has spread to such an extent in the United States that the latest figures show a decline in births attended by midwives.

I base my plea for the development of ophthalmic practice by properly trained doctors upon grounds of public policy and not upon any narrow view of craftsmanship. I make no doubt that if ophthalmic benefit be provided through doctors from one generation of medical students there will be secured such a number of competent practitioners as will give a personnel equivalent to one doctor who does ophthalmic practice to every town of 10,000 inhabitants, who will be able to cope with the demand in the town of his residence and a wide rural district around.

I have hope that our statesmen (and in that term I include the officers of the great friendly societies) will strive for permanent advantage rather than a makeshift.

## CO-ORDINATION OF WELFARE SERVICES.

ADDRESS TO THE WEST HAM INSURANCE COMMITTEE.

BY

HAROLD S. BEADLES, M.R.C.S.,

CHAIRMAN OF THE COMMITTEE.

As time goes on the public services provided under the National Health Insurance Act are unfolding to the view of the student of social affairs a vista of health activity, more beneficial in its results than the promoters of the Act dared to anticipate at its inception. In spite of the many vicissitudes suffered by National Health Insurance administration since 1911—arising mainly out of the war—the financial assistance and medical attendance and treatment provided thereunder have clearly demonstrated that with steadfastness of purpose, and the power of careful organization, there is a possibility of achieving results in this phase of human life which must not be ignored by those responsible for the welfare of the community, if the peoples of the more thickly populated areas of the country are to be rendered capable of withstanding the unnatural strain put upon their bodies and minds by the present artificial existence known as modern civilization. The elements of insurance have been provided for fifteen million persons as against five million previously insured voluntarily.

Nevertheless we are even now only in a position to discern the fringe of the true health standard. What little we can see, however, indicates the more forcibly the nebulous state of a great many of the nation's present health activities in other directions. The full splendour of good health can only be enjoyed by the establishment of well defined and effective relationship between the various particles now wandering more or less haphazardly around the central and local administration of public affairs. The systems of health and public welfare administration which have been built up in this country during generations past, each very good in its service of that particular need which caused its creation, have now become much too numerous for the individual whom they are intended to benefit to understand thoroughly and use to the best advantage. The creation of funds for the operation of such systems is to-day also a matter of much complexity. The operation of the National Insurance Act has demonstrated that continuance of this multiplicity of systems and complexity of finance is entirely unnecessary. It has shown the need for providing complete insurance for workers without the possibility of such workers being at any time "out of benefit." That which has acted so smoothly in health and insurance, so efficiently during the past twelve years can open the way for other public welfare services, local rates for others, precepts, rates, and voluntary subscriptions for others, whilst compulsory contributions in other forms now play a big part in the social scheme. A number of the services have bases of incidence of charge peculiar to themselves and differing materially from those of others.

It is claimed that there is no need for all these varieties. All public services might well be divided into two main categories—namely: (a) imperial—that is, those applicable to the community as a whole; and (b) individual—that is, those applicable to and enjoyed by the individual particularly. In the former there would be included the navy, army, air force, and other defence services; diplomacy, government (central and local); police protection and allied services; education; construction and maintenance of roads; water supply, housing, drainage, and sanitation; prevention of pollution of air, water, and food; control of agriculture, shipping, and transport; medical research, and many others. Under (b) would be grouped financial assistance in time of sickness and accident, maternity and unemployment; widows' and orphans' and old age pensions and allowances; medical attendance and treatment in the fullest sense, including all institutional, dental, ophthalmic, and specialists' services and nursing.

It is the second group (b) with which I am now dealing. Mr. Lloyd George, one year before the passage of the National Insurance Act, 1911, referred to the gigantic task of dealing with the sick, the infirm, the unemployed, and the widows and orphans. This reference, and the fact of his production of the Insurance Act so soon after it was made, indicates the possibility that he, even at that time, realized what an important part insurance could play in the amelioration of some of the ills mentioned. To-day all political parties have announced their intention to alter and extend national insurance against sickness, unemployment, and accident, and to co-ordinate measures to these ends with provision for old age, widowhood, and orphanage. Yet of all the schemes so far expounded not one would seem to aim at total insurance for all social "individual" services.

The Insurance Acts have further shown the inequity of having different payments for different conditions. It is difficult to see why, if sickness is to be the subject of insurance, the benefit

derived therefrom, when sickness falls upon the insured, should be something short of the benefit derived from employment. Sickness places a far greater strain upon the household exchequer than good health. Therefore sickness pay should at least bear adequate proportion to good health pay. At present the sick pay is 15s. a week, while unemployment averages 50s., compensation for accident 50s., and that for old age 10s. Similar benefits of insurance should apply to old age, unemployment, and the other ills to which the great majority of the working people are heir. Subject, of course, to family responsibilities, these should be equal at, say, 50s. for the man, when it would be unnecessary to distinguish whether a person is prevented from working by illness, unemployment, accident, old age, or any other disability. The standard of living given by the insurance benefits should be regulated according to the disability which the benefit is created to counteract. At the same time all the means available for removal of the disabilities insured against should be brought into full operation on behalf of the individual as part of the insurance scheme. These would include domiciliary medical attendance and treatment, institutional treatment (surgical and otherwise), and nursing, and also the finding of employment. National insurance must primarily be for the benefit of the community and not of the individual, and for this reason the premium should cover all time of unemployment from whatever cause arising. It must include all those who now come under the Poor Law. Many of these are the same people, temporarily unemployed, while others are unemployable for various reasons; but the State cannot afford to leave these out if it desires a healthy nation. Some of the unemployable are now the greatest danger to the community.

The funds for the provision of these individual services should be raised in manner somewhat similar to the present system of national insurance so far as they would be collected through the medium of stamps purchasable at the Post Office. There should, however, be one form of stamp for all purposes, the face values being graduated from a minimum to a maximum by not less than one penny. The primary function of the stamped card would be the check it would furnish upon the proper payment of contributions on behalf of the person employed. Contributions should be payable in respect of every person reaching employment age—namely, at the expiration of his or her school age; and should continue to be payable until either the age of 65 is reached—when the old age pension would be payable—or until certain agreed earning has been attained, or until proof that a certain standard of living was assured by private means. Such contributions should be at a rate per pound of earnings—probably sixpence to the worker—and could be charged in suitable proportion between the State, the employer, and the employed. During periods of unemployment through sickness or otherwise the rate of contribution should be paid by the State and the insured person concerned, out of his cash benefits. The State's contribution to the benefits and administration, representing the State's interest in the social welfare of the individual, would be drawn from the funds derived by special taxation and revenues for imperial purposes, or as a first charge upon income tax. The moneys accumulated by the sale of stamps would pass through a central fund, controlled by the State, to local pools controlled by the administering local authorities.

It is estimated that about £230,000,000 per annum would meet the expense of the personal services requirements of the community, this figure being arrived at thus:

Health ... ..	£94,500,000	including cash payments.
Employment ... ..	85,500,000	" " "
Pensions (old age, etc.) ...	100,000,000	" " "
	£280,000,000	

To meet this annual charge a levy of 2s. 6d. would have to be made in respect of every £1 earned in the country, apportionable between the State, the employer, and the insured person. This seems at first sight to be a large proportion of the country's wages bill, but it must be remembered that under this scheme the poor relief rates, a considerable proportion of the ordinary local rates, hospital contributions, and other central and local taxes and rates would disappear, whilst the present contributions under the Health and Unemployment Insurance Acts would also be merged. Moreover, much of the present wasteful method of collection of revenues—State and local—would be swept away.

Reference has already briefly been made to the proposed system of administering the scheme. The State would control the collection of funds and supervise the apportionment thereof among the local authorities responsible for the actual administration of the benefits. These local authorities should be constituted mainly of persons appointed by and from the present county and county borough councils, supplemented by persons appointed by such councils and nominated from various interests concerned with the working of the scheme, due regard being paid in the making of such appointments to experience acquired

by the persons selected in the public services which are to be absorbed thereunder.

Medical benefit is at present administered by Insurance Committees, but only general practitioner attendance is provided for most of the insured, and then only "if in benefit." Additional benefits are provided by some approved societies for some of the insured. It is now clear that the only way to provide complete medical attendance for the whole community is to place it under the control of one body, not separate approved societies or the present Insurance Committees, but an *ad hoc* committee of the county or borough council on the lines of the educational committees, which committee could administer all health matters and properly co-ordinate them.

When contributions are taken compulsorily from a portion of the community the contributors have a right to expect to be provided with equal benefits and on equal terms. The position of the deposit contributors is a serious menace to the general health, and so long as there exists a number of societies approved for the purpose of administration and giving different benefits to their members the name of "national" becomes a farce. The working of the Act has shown some of us that we cannot continue permanently to have such societies approved, and that here again we shall have to set up committees of county and borough councils, which committees will administer not only health insurance but all other forms of social insurance, including those for sickness, accident, unemployment, old age pensions, and widows' pensions, when there will be no necessity for the present Poor Law system.

Our thanks are due to the approved societies for all the work they have done in the past, the friendly societies as the pioneers, and the great industrial insurance companies for the assistance of their wonderful organizations. But we and they must recognize that the time has come for changes marking the next stage in the development of the great social amelioration; and that they, as well as members of Insurance Committees, must find a way to some administrative body more comprehensive in its constitution and more effective in its power.

## Insurance.

### MEETINGS TO DISCUSS MEMORANDUM OF EVIDENCE TO THE ROYAL COMMISSION.

The following meetings have been arranged to consider the draft Memorandum of Evidence to be submitted by the British Medical Association to the Royal Commission on National Health Insurance.

#### Middlesex.

A meeting of all the medical practitioners in the county of Middlesex will be held under the auspices of the Divisions of the British Medical Association and of the Panel Committee on Sunday, January 18th, at 3 p.m., in the Portman Rooms, 59, Baker Street, for the purpose of considering the draft Memorandum of Evidence to be presented to the Royal Commission on National Health Insurance. Dr. H. B. Brackenbury will explain the Memorandum, and discussion will follow. The meeting is intended to assist the discussion which will take place at the meetings of the Divisions which are to be held later. As the matters to be discussed are of vital importance to the whole profession a large attendance is desired. The Portman Rooms are three minutes' walk from Baker Street Station.

#### Morphebone Division.

At 11, Chandos Street, W.1, on Wednesday, January 14th, at 8 p.m.

#### City Division.

At Islington Town Hall, on Tuesday, January 20th, at 9.15 p.m.  
At Shoreditch. Date and place of meeting to be announced later.

#### Kensington Division.

At Kensington Town Hall, on Friday, January 23rd, at 3.30 p.m.

#### Kingston-on-Thames Division.

At the Surbilon Assembly Rooms, Surbilon, on Tuesday January 20th, at 3.15 p.m.

#### Leicishom Division.

At the New Hall, St. Laurence Church, Bramley Road, Gifford S.E.6, on Wednesday, January 14th, at 8.45 p.m.

#### Willesden Division.

At Willesden General Hospital, Harlesden Road, N.W., on Wednesday, January 21st, at 9 p.m.

#### Bromley Division.

At the United Services Club, London Road, Bromley, on Friday, January 16th, at 8.30 p.m.

#### Sheffield Division.

In conjunction with the Sheffield Local Medical and Panel Committees, at the Church House, St. James Street, Sheffield, on Friday, January 16th, at 8.30 p.m.

#### North-East Essex Division.

At the Red Lion Hotel, Colchester, on Friday, January 9th at 3 p.m.

## Meetings to Discuss Memorandum of Evidence.

JAN. 10, 1925]

- Guildford Division.**  
At the Royal Surrey County Hospital, on Thursday, January 22nd, at 3 p.m.
- North and South Suffolk Divisions.**  
In the Council Chamber of the East Suffolk County Council, Ipswich, on Wednesday, January 14th, at 2.30 p.m.
- Gateshead Division.**  
At the offices of the Gateshead Unionist Association, 3, Catherine Terrace, Gateshead, on Sunday, January 11th, at 3 p.m.
- Buckinghamshire Division.**  
In conjunction with the Bucks panel practitioners, at the Crown Hotel, Aylesbury, on Friday, January 16th, at 3 p.m.
- Holland Division.**  
At the White Hart Hotel, Spalding, on Friday, January 16th, at 3 p.m.
- South-Western Branch.**  
At the Royal Cornwall Infirmary, Truro, on Tuesday, January 13th, at 3 p.m.
- Bedford Street, Plymouth, on Thursday, January 14th, at 4.15 p.m.**  
At Goodbody's Restaurant, Bedford Street, Plymouth, on Thursday, January 14th, at 4.15 p.m.
- Derby Division.**  
At the Royal Devon and Exeter Hospital, Exeter, on Thursday, January 15th, at 3 p.m.
- Derby Division.**  
At Derby, on Friday, January 23rd, at 3 p.m. Place of meeting will be announced later.
- Harrogate Division.**  
At the Imperial Café, Harrogate, on Tuesday, January 13th, at 8.30 p.m.
- South-Eastern Counties Division (Edinburgh Branch).**  
At the Railway Hotel, Newtown St. Boswells, on Wednesday, January 14th, at 3 p.m.
- English Division (Border Counties Branch).**  
At the County Hotel, Carlisle, on Tuesday, January 13th, at 3.30 p.m.
- Furness Division.**  
At the Criterion Restaurant, Cornwallis Street, Barrow, on Wednesday, January 14th, at 3.15 p.m.

As pointed out in the leading article published in the JOURNAL of January 3rd, page 30, it is of great importance that every medical practitioner, whether serving under the Insurance Act or not, and whether a member of the British Medical Association or not, should attend the meeting in his district. The draft Memorandum of Evidence to be submitted to the Royal Commission was published in the SUPPLEMENT of January 3rd, and it is hoped that members attending will take it to the meetings.

### A LOCAL INQUIRY INTO RHEUMATIC DISEASE.

We have received for information a circular letter which the Leicestershire Insurance Committee has sent out to the insurance practitioners in its area. It consists of a memorandum embodying the conclusions arrived at from the study of the Ministry of Health report on the incidence of rheumatic diseases, published early last year, and also of an inquiry into various factors which may have an etiological bearing on these diseases in Leicestershire. Observations have been asked as to—

1. Cellar dwellings (if any).
2. Factory conditions and name of principal industry.
3. Information as to dental and tonsillar sepsis among insured persons and dependants (percentage).
4. Whether doctor would approve of a general scheme for mouth and teeth examination of insured persons, and furnish suggestions thereto.
5. State actual conditions and places in your district which require attention of sanitary, roads, and health improvements.
6. Recommendation as to health propaganda in various forms.

We notice, however, that there is no inquiry as to the number of cases of rheumatism occurring in each practitioner's district, but we presume that the intention will be to obtain these figures from the insurance cards. Only two and a half weeks have been allowed for the filling up and returning of the schedules, so it would appear that all that is hoped for at this stage is a general impression of the conditions obtaining in Leicestershire with a view to further action. We feel sure that the bringing of the insurance practitioner into the scheme of preventive medicine can only result in good to the national health.

### LONDON PANEL COMMITTEE.

A MEETING of the London Panel Committee was held on December 16th, 1924, under the chairmanship of Dr. H. J. CARNALL. An estimate of the expenditure of the Panel Committee for 1925 was £5,300, representing 0.44d. per insured person. The expenditure for 1924 was £2,772.

**Complaints against Practitioners.**  
The findings of the Medical Service Subcommittee in certain cases were criticized. In a case against a practitioner recently

investigated by the subcommittee, the practitioner had put in a statement which he had obtained from the insured person himself to the effect that there was no urgency in the case. The subcommittee thereupon reported to the Insurance Committee that it deprecated the action of the practitioner in obtaining such a statement from the insured person, as it made the consideration of the matter more difficult. After some discussion, the Panel Committee agreed to a resolution informing the Ministry of Health of its opinion that the action of the practitioner in obtaining the statement from the insured person was quite reasonable and justifiable. Dr. CARDALLO dissented from this view, and held that in the circumstances of the case the recommendation of the Medical Service Subcommittee was a sound one. Dr. CARDALLO also took exception to another resolution before the Panel Committee in which it was called upon to express its disagreement with the position upon a practitioner. Dr. SRAATON, who was responsible for the resolution, said that it did seem that in this somewhat exceptional case the decision of the subcommittee was opposed to the facts elicited, and that the punishment meted out was too severe. The Committee, however, agreed to an amendment to bring to the notice of the Insurance Acts Committee a case in which the Medical Service Subcommittee had decided to hear a complaint lodged by an approved society against a practitioner notwithstanding the fact that the period of six weeks allowed under the regulations had been exceeded.

After a long discussion, and after hearing a report from its representatives on the Medical Service Subcommittee, the Panel Committee decided to bring to the notice of the Ministry of Health certain matters in controversy relating to the election of chairman of the subcommittee, and decided that its representatives—in whom it passed a vote of confidence—should not attend the meetings of the subcommittee until the matter was adjusted.

**A Holiday Substitute Scheme.**  
It was reported that the "holiday locum" scheme under the aegis of the Committee had been worked by a group of practitioners on the boundary between the boroughs of Marylebone and Paddington with quite successful results, and a similar scheme was authorized for 1925.

## Correspondence.

### ROYAL COMMISSION ON NATIONAL INSURANCE.

SIR,—At the meetings of the profession when the draft of the Memorandum of Evidence proposed to be given by the British Medical Association before the Royal Commission is considered some Divisions will have present members of the Council, or of the committees which have considered the question, and some will have "official" speakers from the central office and elsewhere to explain the document to them. The side of the question put forth in the evidence is thereforo likely to be fully elucidated in these centres. But a number of Divisions will have no guidance of this sort, and it is right that they, as well as those who have the official explanations, should be afforded the chance of hearing the arguments against some portions of the proposed evidence and considering facts which are not clearly set forth in the draft, so that they may obtain a clear understanding of both sides of the matter before answering the very important questions set down.

Everyone who has worked at or studied the subject will be in cordial agreement with the major portion of the proposed evidence. If there is to be a health service on insurance lines it should be made as perfect as possible in every way, and should include specialist and consultant services and laboratory facilities. The question of attendance at conferences is for those to decide who will have to officiate, and everyone will agree with an attempt to improve the conditions under which panel practice is carried on, and to free it as far as possible from red tape of every description. But the proposed inclusion of the dependants of insured persons in an insurance scheme is quite a different proposition, and, as Dr. Cox rightly states in his letter to Secretaries of Divisions and committees, dated December 19th, 1924, would seriously threaten the practices of those general practitioners who are not on the panel. The fact that these committees which considered the evidence, and practically only voiced by Dr. John Stevens and myself at the Council meeting, is one of the reasons for this letter, in order that the Divisions before voting may be able to consider both sides of the question.

The proposed Memorandum of Evidence suggests that the dependants only of the lower paid insured persons should be included, and proposes various safeguards. But in answer to a question at the Council meeting the fact appeared that

the imposition of an income limit on insured persons was the only reliable method by which it was possible to determine whether the dependants of any particular person came within the scheme or not. Anyone who is conversant with the subject knows perfectly well that no Royal Commission will recommend, nor will any Government venture to impose, any income limit whatever on manual workers. Those of us who had to urge this point during the negotiations on the Insurance Bill had this fact thoroughly impressed on us with the most perfect frankness.

The votes of millions weigh more than those of thousands. This being so, it may be taken that the Divisions must vote for all or none. Any attempt to get in the lower paid only is impossible and illusory. The Association, ever since I have known anything about its policy, has always held that contract practice is the least desirable form of practice, and should only be undertaken for those who are quite unable to provide private attendance for themselves. If all the dependants are to be included (making a total of 38½ million), then well over 80 per cent. of the population will get their medical attendance under contract by compulsion. Free from compulsion, such a scheme would fail entirely.

The objections to this state of affairs are:

1. The deepening, accentuation, and perpetuation of the objectionable distinction between "panel" and "non-panel" practitioners, which is bad in the eye both of the public and the profession. I have many times heard it urged that a panel practitioner is also a private practitioner. In these circumstances this would cease to be the fact in a very large number of cases. Every vestige of private practice in thickly populated industrial districts would go by the board, and only those practising in country or residential districts would retain any private patients at all.

2. If the Association, claiming to represent the profession, gives evidence that it is prepared to recommend that 80 odd per cent. of the population shall be attended as part of a State-aided scheme under contract, then a tremendous weapon will be placed in the hands of those in favour of a whole-time State medical service, who would at once urge that such a service would be easier to administer, discipline, and control, as well as much cheaper, and that if the profession were ready for 80 per cent. they would soon swallow the other 20 per cent. It has been argued that to suggest the possibility of such a service is a "bogey." But it is now within the practical politics of one party at least; and *verbum sap.*

3. It would be impossible at present to find sufficient doctor-power to work such a scheme. There are about 14,500 practitioners on the insurance panels, and it is extremely unlikely that many of those outside would be forced on to them. Therefore the 38½ million of insured persons and dependants would have to be divided among this 14,500, giving about 2,700 to each doctor. If it were possible to spread this average evenly over all the kingdom it would be a practicable proposition. But in the rural areas there would not be enough inhabitants to give each practitioner this number, and in the industrial districts there would be a great deal too many. Those of us who worked the Central Medical War Committee will remember the chaos in face of the 1918-19 influenza epidemic, when there was too large a number of patients for each doctor left in civil practice. In addition, the amount of work which would be required from anyone undertaking the treatment of insured women and insured young children would be enormous. The insured mother with her insured offspring would very rightly require much more attention than an ordinary insured worker—male or female.

4. The financial side requires careful consideration. The cost of the lay administration of the Insurance Act is about £7,000,000 a year. With an increase of insured persons of 150 per cent. this expense would increase *pari passu*. Either the number of officials or their respective salaries would go up like a rocket. It is only the altruistic doctor who is always expected to do more work for lower fees. With regard to the capitation fees for medical benefit, the doctor would be expected to insure that part of the population with the greatest expectation of sickness at a premium perhaps less than that paid for a healthy worker.

5. This draft of evidence has been prepared and submitted practically by the Insurance Acts Committee. Those practitioners who would be very materially affected if the dependants were included have only a nominal representation on that committee, and very probably in most cases know very little of the suggested removal of a large number of their patients from their care unless they consent to swallow their principles and engage in panel practice. No decision on this exceedingly important question should be made by any Division unless the members have had these facts and arguments set before them

much more clearly than they are displayed in the draft. It is proposed that the final vote on the question shall be given by a meeting of the Representative Body together with the members of the Panel Conference, almost all of which latter body are either engaged in practice under the Insurance Act or are taking part in its administration. Why not strengthen the gathering by including an equal number of non-panel men? This is, of course, impossible, but is logical and fair.

In conclusion, in my opinion there is a great opportunity for the Association to give wise evidence and press for everything possible to improve the present system, and remove those defects which press hardly both on the insured person and his doctor, but not to risk splitting the profession in chase of an impossible ideal, the pursuit of which might easily land us in a State service which would be detrimental to the doctor, more detrimental to the study of the science and art of medicine and surgery, and disastrous to the sick person.—I am, etc.,

London, W.2, Jan. 5th.

E. B. TURNER.

SIR.—The British Medical Association has let slip a golden chance of doing a national service. Like the Annual Representative Meeting of 1922, which carefully skirted round the issue, so in the evidence to be given before the Commission the Association refuses the opportunity thrust upon it to discuss the absolutely vital question whether the Act does not increase national poverty in depth and area; and yet it has (for the first time in my knowledge) made this forward step that it begins by the admission that this scheme which "has justified its existence" may, after all, be waste; the money, it allows, might have been better spent.

There is no doubt that in the public eye judgement will go by default. If the Association does not discuss the principle, but does discuss the details, even advising extensions, it will be held to have approved that principle. I know that many medical men feel a certain dissatisfaction with an attitude which suggests that our citizenship should be subordinate to professionalism. We want to know what is good for the poor, and, so far as in us lies, guide the nation in the light of that knowledge.

All history shows that national health depends on national standard of living. Now it is plainly impossible to raise that standard of living by a tax on production. No one can deny that the employers' contribution is such a tax. It bears hard on the small employer; everyone has noticed that. When he can raise prices (and he has not yet failed to do so) it hurts the larger employer not at all. It bears hard on the working man with a young family; unless it cause unemployment (and everyone has known cases) it is trivial for the young and unmarried. It hits cruelly where it means to miss; it misses where it aims to hit.

It is a national question, and the position taken by the Association may have consequences incalculable. I appeal to those men who have hitherto stood aloof, especially consultants, feeling that it is no concern of theirs. National welfare concerns us all. Everyone knows how the Labour party—and others to-day—are obsessed by the notion that the State purse is bottomless. For humanity's sake, and England's, I appeal to them to discourage that pathetic and dangerous fallacy.

The Royal Commission has consented to receive evidence on the principle. To make it effective the support of a number of doctors is desirable. Will sympathizers who read this note send me a postcard with their names and any friends' names (not to pledge themselves to any particular doctrine) to say that they deprecate any extension of the Act till the basic principle has been thoroughly considered?—I am, etc.,

29, Daniel Street, Bath, Somerset,  
Jan. 7th.

B. G. M. BASKETT.

#### Locumtenents' Bureaux.

SIR.—There is a mistake in the report of Council on page 10, second column, of the SUPPLEMENT of January 3rd, where, in the discussion on the proposed medical bureaux, I am represented as having said, "The benefits will be strictly confined to men during the first four years after qualification." As a matter of fact, the report of my Committee was to the effect that this was one of the questions which was reserved for further consideration.—I am, etc.,

Doxford, Jan. 5th.

S. MORTON MACKENZIE.

#### Advertisements on Certificate Forms.

SIR.—Whenever I meet with a certificate, or other statutory form, which bears a trade advertisement I write in bold letters across the advertisement "Not recommended by me." If this practice were generally followed the nuisance would soon cease.—I am, etc.,

Whitby, Jan. 2nd.

J. G. ROSS.

JAN. 10, 1925]

## Naval and Military Appointments.

Panel Consultants.  
SM.—As it appears to be highly probable that the question of consultation with specialists under the panel system will be discussed by the Royal Commission on National Insurance, I desire to point out that a large trade union of non-manual workers has initiated a scheme for securing consultations which has been in full working order for some years.

At the office of the union a list of specialists is kept to meet the requirements of individual members. On application to the secretary the appropriate consultant is communicated with, and he is asked to make an appointment in a letter to the member. At the consultation the member presents a card of introduction, and pays the agreed fee at his own expense before leaving. Several years ago I was asked by the secretary to join the staff of consultants at half the usual fee, which was then two guineas. When, however, the scale of fees generally was raised during the war I was informed that for the future the fee would be one and a half guineas.

In the event of a member requiring a home consultation I am asked what the fee would be, and here again half the fee usually charged is that generally suggested. On an agreement being arrived at the member's own doctor is communicated with and an appointment made. In my own experience there has never been any friction between the parties met and their independence maintained. I may add that the members fully appreciate the advantages the scheme offers.—I am, etc., A. Z.

## Naval and Military Appointments.

ROYAL NAVAL MEDICAL SERVICE.  
SURGEON CAPTAIN R. H. MONUMENT, O.B.E., to the President, additional for three months' post-graduate course.  
The following Surgeon Commanders have been placed on the retired list with the rank of Surgeon Captain: N. H. Harris, A. C. W. Newport, C.V.O., R. W. Stanstreet, T. E. Blunt to the Dido; B. S. Robson to the O'Connell to the Agamemnon.

Lieut.-Colonel W. F. Ellis, O.B.E., is placed on the half-pay list on account of ill health.  
Major W. D. O. Kelly, D.S.O., to be Lieutenant-Colonel to complete establishment.  
Major S. McK. Saunders retires on retired pay.  
Major (now Major) W. H. O'Riordan, M.C., to be acting Major from October 28th, 1917, to March 30th, 1919.  
Captain (now Major) W. H. O'Riordan, M.C., to be acting Major from October 28th, 1917, to March 30th, 1919.  
Captain T. Young relinquishes his temporary rank of Major on ceasing to be employed as a Deputy Assistant Director of Hygiene.  
Captain F. A. Roddy retires, receiving a gratuity.  
Captain H. S. Griffith retires, receiving a gratuity.

ROYAL AIR FORCE MEDICAL SERVICE.  
Squadron Leader T. S. Rippon, O.B.E., to be Wing Commander; Squadron Leader E. Huntley to be honorary Wing Commander.  
Flight Lieutenants W. R. Forbes and J. W. H. Stoll to be honorary Squadron Leaders.  
Squadron Leaders A. E. Henton to R.A.F. Depot; (Honorary Squadron Leader) F. W. Squire, T.D., to Central Flying School, Updon.  
Flying Officers W. A. Beck and J. Parry-Evans to R.A.F. Depot.

REGULAR ARMY RESERVE OF OFFICERS.  
ROYAL ARMY MEDICAL CORPS.  
W. G. Hazelton, late Cadet, Belfast University Contingent, O.T.C., to be Lieutenant.  
SUPPLEMENTARY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS.  
A. S. Burns to be Lieutenant.

INDIAN MEDICAL SERVICE.  
Major-General J. Jackson, O.B.E., E.H.P., has retired.  
Lieut.-Colonel R. W. Knox, D.S.O., to be Colonel, vice Colonel H. J. E. Bannard, D.S.O., K.H.P., promoted to be Major-General.  
Major L. H. L. Mckenzie, an officiating Agency Surgeon, is granted leave on average pay for eight months, combined with leave on half average pay for one year and twenty-four days (November 3rd, 1924).  
Major E. Stevenson, on officiating Agency Surgeon, is posted as Agency Surgeon, Gilgit (November 3rd, 1924).  
Major H. Stott, O.B.E., are placed temporarily at the disposal of the Government of the United Provinces, with effect from date of his appointment as Professor of Pathology, King George's Medical College, Lucknow.

The promotion to his present rank of Major H. B. Scott, O.B.E., is ante dated from September 1st, 1918, to March 1st, 1918.  
The promotion to his present rank of Major A. N. Thomas, D.S.O., is ante dated from July 27th, 1919, to January 27th, 1919.  
Major W. D. H. Stevenson, C.I.E., relinquished the temporary rank of Lieutenant-Colonel on vacating the appointment of Assistant Director-General, I.M.S., on February 10th, 1922.  
The services of Captain C. G. Martin, an officer of the Medical Research Department, are placed temporarily at the disposal of the Government of Madras for appointment as officiating Assistant Director, King Institute of Preventive Medicine, Guindy.  
The services of Captain R. C. Mohitra, O.B.E., are placed permanently at the disposal of the Government of the Punjab.

## TERRITORIAL ARMY.

ROYAL ARMY MEDICAL CORPS.  
Major (Prov.) A. F. Lee, M.C., is confirmed in his rank.  
Major A. Walker, D.S.O., T.D., resigns his commission and retains the rank of Major, with permission to wear the prescribed uniform.  
Captain E. Phillips, D.S.O., M.C., R.A.M.C., to be Divisional Adjutant, 54th (East Anglian) Division, vice Major R. K. Mollam, R.A.M.C.  
Captain J. F. Edmiston to be Major, with precedence from June 3rd, 1924.  
Captain H. A. Lucas resigns his commission and is granted the rank of Major.

## COLONIAL MEDICAL SERVICES.

Dr. J. C. MacNaughton, M.O., Tonganyiko, transferred from Tabora to Bukoba.  
Dr. Thomas Clinch appointed Government Medical Officer, Fiji.  
Dr. Nora A. Robinson appointed Medical Officer, Medical Department, Gold Coast.

Salary at the rate of £150 per annum. (4) House-Surgeon. Salary at the rate of £150 per annum. (5) House-Physician. Salary at the rate of £150 per annum. (6) House-Surgeon. Salary at the rate of £150 per annum. (7) House-Physician. Salary at the rate of £150 per annum. (8) House-Surgeon. Salary at the rate of £150 per annum. (9) House-Physician. Salary at the rate of £150 per annum. (10) House-Surgeon. Salary at the rate of £150 per annum. (11) House-Physician. Salary at the rate of £150 per annum. (12) House-Surgeon. Salary at the rate of £150 per annum. (13) House-Physician. Salary at the rate of £150 per annum. (14) House-Surgeon. Salary at the rate of £150 per annum. (15) House-Physician. Salary at the rate of £150 per annum. (16) House-Surgeon. Salary at the rate of £150 per annum. (17) House-Physician. Salary at the rate of £150 per annum. (18) House-Surgeon. Salary at the rate of £150 per annum. (19) House-Physician. Salary at the rate of £150 per annum. (20) House-Surgeon. Salary at the rate of £150 per annum. (21) House-Physician. Salary at the rate of £150 per annum. (22) House-Surgeon. Salary at the rate of £150 per annum. (23) House-Physician. Salary at the rate of £150 per annum. (24) House-Surgeon. Salary at the rate of £150 per annum. (25) House-Physician. Salary at the rate of £150 per annum. (26) House-Surgeon. Salary at the rate of £150 per annum. (27) House-Physician. Salary at the rate of £150 per annum. (28) House-Surgeon. Salary at the rate of £150 per annum. (29) House-Physician. Salary at the rate of £150 per annum. (30) House-Surgeon. Salary at the rate of £150 per annum. (31) House-Physician. Salary at the rate of £150 per annum. (32) House-Surgeon. Salary at the rate of £150 per annum. (33) House-Physician. Salary at the rate of £150 per annum. (34) House-Surgeon. Salary at the rate of £150 per annum. (35) House-Physician. Salary at the rate of £150 per annum. (36) House-Surgeon. Salary at the rate of £150 per annum. (37) House-Physician. Salary at the rate of £150 per annum. (38) House-Surgeon. Salary at the rate of £150 per annum. (39) House-Physician. Salary at the rate of £150 per annum. (40) House-Surgeon. Salary at the rate of £150 per annum. (41) House-Physician. Salary at the rate of £150 per annum. (42) House-Surgeon. Salary at the rate of £150 per annum. (43) House-Physician. Salary at the rate of £150 per annum. (44) House-Surgeon. Salary at the rate of £150 per annum. (45) House-Physician. Salary at the rate of £150 per annum. (46) House-Surgeon. Salary at the rate of £150 per annum. (47) House-Physician. Salary at the rate of £150 per annum. (48) House-Surgeon. Salary at the rate of £150 per annum. (49) House-Physician. Salary at the rate of £150 per annum. (50) House-Surgeon. Salary at the rate of £150 per annum. (51) House-Physician. Salary at the rate of £150 per annum. (52) House-Surgeon. Salary at the rate of £150 per annum. (53) House-Physician. Salary at the rate of £150 per annum. (54) House-Surgeon. Salary at the rate of £150 per annum. (55) House-Physician. Salary at the rate of £150 per annum. (56) House-Surgeon. Salary at the rate of £150 per annum. (57) House-Physician. Salary at the rate of £150 per annum. (58) House-Surgeon. Salary at the rate of £150 per annum. (59) House-Physician. Salary at the rate of £150 per annum. (60) House-Surgeon. Salary at the rate of £150 per annum. (61) House-Physician. Salary at the rate of £150 per annum. (62) House-Surgeon. Salary at the rate of £150 per annum. (63) House-Physician. Salary at the rate of £150 per annum. (64) House-Surgeon. Salary at the rate of £150 per annum. (65) House-Physician. Salary at the rate of £150 per annum. (66) House-Surgeon. Salary at the rate of £150 per annum. (67) House-Physician. Salary at the rate of £150 per annum. (68) House-Surgeon. Salary at the rate of £150 per annum. (69) House-Physician. Salary at the rate of £150 per annum. (70) House-Surgeon. Salary at the rate of £150 per annum. (71) House-Physician. Salary at the rate of £150 per annum. (72) House-Surgeon. Salary at the rate of £150 per annum. (73) House-Physician. Salary at the rate of £150 per annum. (74) House-Surgeon. Salary at the rate of £150 per annum. (75) House-Physician. Salary at the rate of £150 per annum. (76) House-Surgeon. Salary at the rate of £150 per annum. (77) House-Physician. Salary at the rate of £150 per annum. (78) House-Surgeon. Salary at the rate of £150 per annum. (79) House-Physician. Salary at the rate of £150 per annum. (80) House-Surgeon. Salary at the rate of £150 per annum. (81) House-Physician. Salary at the rate of £150 per annum. (82) House-Surgeon. Salary at the rate of £150 per annum. (83) House-Physician. Salary at the rate of £150 per annum. (84) House-Surgeon. Salary at the rate of £150 per annum. (85) House-Physician. Salary at the rate of £150 per annum. (86) House-Surgeon. Salary at the rate of £150 per annum. (87) House-Physician. Salary at the rate of £150 per annum. (88) House-Surgeon. Salary at the rate of £150 per annum. (89) House-Physician. Salary at the rate of £150 per annum. (90) House-Surgeon. Salary at the rate of £150 per annum. (91) House-Physician. Salary at the rate of £150 per annum. (92) House-Surgeon. Salary at the rate of £150 per annum. (93) House-Physician. Salary at the rate of £150 per annum. (94) House-Surgeon. Salary at the rate of £150 per annum. (95) House-Physician. Salary at the rate of £150 per annum. (96) House-Surgeon. Salary at the rate of £150 per annum. (97) House-Physician. Salary at the rate of £150 per annum. (98) House-Surgeon. Salary at the rate of £150 per annum. (99) House-Physician. Salary at the rate of £150 per annum. (100) House-Surgeon. Salary at the rate of £150 per annum.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.—House-Physician. Salary £100 per annum.  
ST. LEONARDS-ON-SEA: BUCHANAN HOSPITAL.—House-Surgeon (woman). Salary £100 per annum.  
ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.13.—Honorary Assistant Physician.  
SOUTHAMPTON HOSPITAL, East Dulwich Grove, S.E.—Mole Assistant Medical Officer. Salary at the rate of £300 per annum.  
SYDNEY UNIVERSITY.—Professor of Obstetrics. Salary £1,100 per annum.  
WEST LONDON HOSPITAL, Hammersmith Road, W.6.—(1) Honorary Medical Registrar; honorarium £100 per annum. (2) Honorary Obstetric Registrar. Registrar; honorarium £100 per annum. (3) Resident Medical Officer. Salary at the rate of £250 and £150 per annum respectively.  
WOLVERHAMPTON AND STAFFORDSHIRE HOSPITAL.—(1) Resident Medical Officer. (2) House-Surgeon. Salary at the rate of £250 and £150 per annum respectively.

CERTIFICATE FACTORY SURGEONS.—The Chief Inspector of Factories announces the following recent appointments: Bovey Tracey (Devon), St. Just (Cornwall), Staplehurst (Kent).

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

## British Medical Association.

### ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

The following Memorandum of Evidence (as approved by the Council on December 17th, 1924) was submitted on behalf of the British Medical Association to the Royal Commission on Lunacy and Mental Disorder on Wednesday, January 14th. The Association's witnesses were: Dr. R. Langdon-Down (Chairman of the Association's Committee on Lunacy and Mental Disorder), Dr. J. W. Bone, Dr. F. H. Edwards, Dr. C. O. Hawthorne, Mr. E. W. G. Masterman, Dr. Christine Murrell, and Sir Jenner Verrall.

#### MEMORANDUM OF EVIDENCE GIVEN ON BEHALF OF THE ASSOCIATION.

##### INTRODUCTORY.

1. The British Medical Association is a voluntary organization of the medical profession; it comprises representatives of every form of medical practice and includes both practitioners who deal with the mentally disordered in various special ways and those who meet such patients in the usual course of general practice. The Members of the Association, now numbering over 28,400, are organized throughout the British Empire in local units called Divisions and in combinations of Divisions called Branches. By means of this local machinery, and with the help of its weekly organ, the *BRITISH MEDICAL JOURNAL*, the Association is able to inform and to collect the opinions of the main body of the medical profession, and in preparing this Memorandum the Council of the Association has utilized the experience and views of every type of medical practitioner.

2. When the Council of the Association learned that a Royal Commission on Lunacy and Mental Disorder (as regards England and Wales) was to be set up by the Government, it appointed a Special Committee to consider possible modifications of the Lunacy Laws, to prepare evidence for submission on behalf of the Association to the Royal Commission; and to appoint witnesses to give such evidence.

3. The personnel of the Special Committee is as follows:

- R. LANGDON-DOWN, M.B., B.Chir., M.R.C.P. (London). Member Medico-Psychological Association, Chairman of Lunacy Law Committee, British Medical Association.
- G. F. BARNHAM, M.D., Member Medico-Psychological Association, Medical Superintendent London County Mental Hospital, Claybury.
- R. A. BOLAM, O.B.E., LL.D., M.D., F.R.C.P. (Newcastle-on-Tyne). Chairman of Council, British Medical Association.
- \*J. W. BONE, M.B., C.M. (Luton).
- \*H. B. BRACKENBURY, M.R.C.S., L.R.C.P. (Hornsey). Chairman of Representative Body, British Medical Association, Vice-President Central Association Mental Welfare.
- F. H. EDWARDS, M.D., M.R.C.P. (London). Member Medico-Psychological Association, Medical Superintendent Camberwell House.
- J. BASIL HALL, M.B., M.Chir., F.R.C.S.Ed. (Bradford). President British Medical Association.
- N. BISHOP HARMAN, M.B., B.Chir., F.R.C.S. (London). Treasurer British Medical Association.
- BERNARD HART, M.D. (London). Member Medico-Psychological Association, late Medical Superintendent Northumberland House Asylum.
- C. O. HAWTHORNE, M.D., F.R.C.P., F.R.F.P. and S. (London). Consulting Physician Hampstead and North-West London Hospital.
- \*J. A. MACDONALD, LL.D., M.D. (Taunton). Consulting Physician Taunton and Somerset Hospital.
- E. W. G. MASTERMAN, M.D., F.R.C.S. (London). Medical Superintendent St. Giles Hospital.
- \*CHRISTINE MURRELL, M.D. in Mental Diseases and Psychology (London). Late Clinical Assistant Northumberland County Asylum.
- \*SIR ALFRED J. RICE-OKLEY, C.B.E., M.D. (London).
- A. F. TREDGOLD, M.D. (London).
- \*E. B. TURNER, F.R.C.S. (London).
- SIR JENNER VERRALL, LL.D., M.R.C.S., L.R.C.P. (Leatherhead). Consulting Surgeon Sussex County Hospital.

\*In General Practice.

4. The Association in approaching the questions submitted to the Royal Commission has endeavoured to keep in mind the principle that the interests of the patient as a sick person should be the first consideration. Subject to this principle the Association desires to give due weight to the claims of the public as a whole for protection against any improper restriction of individual liberty on the one hand and against the risks which attach to the inefficient

control of persons of unsound mind on the other. In addition are to be considered the claims of the medical profession for adequate safeguards in carrying out the difficult and responsible duties placed in the hands of its individual members.

5. The Committee invited and has received and considered suggestions from Medical Superintendents of Poor Law Infirmaries and has had also the assistance and collaboration of several representative general practitioners of great experience.

6. On a previous occasion (*viz.*, in April, 1912) the Association laid before the Government proposals dealing with the treatment of patients suffering from mental disorder in its early stages, but for the purpose of the present inquiry the subject has been fully and freely reconsidered.

#### PRINCIPAL OBJECTS FAVOURED.

7. The principal objects favoured in this Memorandum are briefly as follows:

(a) To meet, as far as possible, the susceptibilities of the public with a view to minimize the objections which prevent patients from accepting proper treatment at the earliest possible moment. (*Vide paras. 24-26.*)

(b) To avoid the need for a formal Reception Order for mental patients whose symptoms, though acute, are likely to be short-lived, in the hope that the recovery of the patient may render such an Order unnecessary. (*Vide paras. 40-44.*)

(c) To provide opportunities for the treatment, on a voluntary basis and under approved conditions, of suitable patients, whether in one of the existing types of institution or in hospitals or clinics or under private care. (*Vide paras. 36-39.*)

(d) To urge the provision and continuation of such kinds of accommodation as shall supply the needs of patients suffering from different forms and degrees of mental disorder; to meet the position created by differences in the social and financial status of such patients; and to advocate, if the ends here defined require it, the removal of the ban on any increase in the number of "licensed houses" (Section 207 (6) of the Lunacy Act 1890). (*Vide paras. 52-55.*)

(e) To secure as far as possible uniformity of procedure in the certification alike of private and of other patients, and in particular to affirm the advisability of two medical certificates for submission to any judicial authority who is asked to issue a Reception Order. (*Vide para. 71 (g).*)

(f) To claim for practitioners who sign medical certificates under the Lunacy Act the immunities granted to witnesses in Courts of Law. (*Vide para. 58.*)

(g) To amend the wording and procedure of the Reception Order and the accompanying documents as hereinafter explained in detail. (*Vide paras. 30-35.*)

(h) To revise the existing conditions under which Voluntary Boarders may be accepted. (*Vide paras. 36-39.*)

(i) To make suitable provision for the after-care of patients leaving institutions, with special regard to collaboration between the patient's private medical attendant and the authorities who may have had charge of the patient. (*Vide para. 48.*)

(j) To preserve the authority of central administration, except in so far as the administration of property is concerned. (*Vide para. 19.*)

8. The Association recognizes that mental disorders differ from other ailments in that the proper treatment of the patient may necessitate, either for his own good or for the protection of his family or the public, interference with his liberty of action; and further, that the patient may be prevented by the nature of his illness from forming a proper judgement on the measures necessary for his welfare. Consequently in the scheme of treatment there must be introduced safeguards which are not necessary in dealing with ordinary bodily ailments where the mind is not affected.

9. Those engaged in the preparation of this Memorandum who were not fully familiar with the law on the subject have been much impressed by the numerous and effective provisions designed for the due protection of the patient's

rights. (Appendix D.) Where the law appears to be defective is in the unsatisfactory character of its terminology, in the differences made in the treatment of patients because of differences in social or financial standing, in a failure to regard the person of unsound mind primarily as a patient—a sick person—and in the failure to provide adequate facilities for treatment without a Reception Order.

#### TERMINOLOGY.

10. Any reconsideration of the Lunacy Acts suggests some elucidation and amendment of the terminology employed. For example, for various reasons a general desire has been expressed that the term "lunatic" should be discarded, and by the passing of the Mental Deficiency Act 1913 the inclusion of the term "idiot" in the Lunacy Acts is rendered both superfluous and anomalous. The word "pauper," although clearly enough defined in the Lunacy Act of 1890, is objectionable on account of its wider significance outside the Act, and its use, in existing circumstances, is frequently unjust.

Again, the substitution of the term "mental hospital" for the old term "asylum" may be justified because it expresses better the modern attitude towards the treatment of mental disorder.

11. Of the two main divisions of mental abnormality—*viz.*, mental deficiency and mental disorder—the Commission is, it is understood, concerned only with the latter, and this Memorandum accordingly confines itself to the discussion of mental disorder, using this term to cover all kinds and degrees of departure from the normal other than mental deficiency.

Within this division many types and forms have been recognized by medical writers, but for the present purpose medical classification, subdivision and definition, so far from being helpful, would be a hindrance.

What has to be considered from the point of view of law and administration is rather the practical measures and arrangements that are called for by any individual case and not the precise nosological classification of the patient's disorder.

12. Broadly speaking, from this point of view there are mental disorders which call for measures of control, and others for which, at all events in some stages, measures of control are not necessary although other kinds of treatment may be required. "Mental disorders" will thus include both grave and mild cases, and the very beginnings of disorder on the one hand and its latest manifestations on the other.

13. It is convenient that some brief and acceptable name should be given to each of these two groups.

14. In the Lunacy Acts the name given to a patient who is a proper person to be taken charge of and detained for care and treatment is "lunatic." If the term "lunatic" is dropped, as is here suggested, the expression "of unsound mind," which is used in the Act alternatively to "lunatic," would seem to be the most suitable one for this group.

15. As, however, there has been a tendency of recent years to use the expression in a somewhat lax and general way it would seem best to give it a precise definition and to confine its use to the particular group of cases now under consideration.

16. The definition suggested is:

"Persons of unsound mind" means persons who by reason of mental disorder may properly be taken charge of and detained for care and treatment."

17. Mental disorder would thus be divided into two groups—*viz.*, (a) the "mentally unsound," and (b) the "mentally ailing"—the former being those proper to be taken charge of and detained, if necessary, and the latter not requiring detention.

18. The need for such definitions is particularly emphasized when the provisions of Section 315 of the Lunacy Act 1890 are considered. Here, unless the phrase "a person of unsound mind" were limited as in the above definition, the section would forbid the reception and treatment in nursing homes of patients who though mentally disordered do not require detention or control.

19. Form 16 of the Lunacy Act 1890—the certificate

dealing with a person entitled to payments from a public department—states that he is “by reason of mental disability unable to manage his affairs.” This expression seems a useful one where it is intended to indicate the need for measures of control of the patient’s property and affairs, but not necessarily of his person; and it might well be used in place of the expression “of unsound mind” in Section 116 (c) of the Lunacy Act 1890.

20. “Mental infirmity arising from disease or age” is an expression used in Section 116 (d), and as it seems to mean much the same as “mental disability” the latter might well take its place for the sake of uniformity.

21. Such a nomenclature as is suggested in paras. 12 to 20 would not be at variance with present usage, is valuable from the point of clearness, distinguishes between different types of arrangement for treatment, and gives due consideration to the susceptibilities of patients and their friends. In addition, it gives a definitely recognized place to those cases which are neither normal in mind nor so mentally disordered as to require measures of control.

22. Accordingly it is suggested that any future Act should be called the “Mental Disorders Act,” and in it the words “lunatic” and “pauper” should not be used.

23. The following scheme shows what is intended in tabular form:

#### CRITICISM OF PRESENT PROCEDURE.

24. More important, however, than the terms used, if the best possible is to be done for those who are mentally disordered, are the arrangements provided and the conditions governing them.

25. The reluctance of patients and their friends to accept treatment under existing arrangements is ascribed partly to unwillingness to enter a place known to be devoted to the treatment of persons of unsound mind and partly to unwillingness to apply for a Reception Order by a judicial authority with its necessary formalities and consequences. (As an example of the kind of thing which should be avoided, the Association would suggest that any patient who is being treated in a Poor Law Infirmary and whose maintenance, in part or in whole, is refunded either by himself or on his behalf, should not be compelled to wear clothing provided by the Poor Law Guardians.) The Reception Order undoubtedly puts a seal of a formal and semi-public nature on the patient’s mental disorder, and this will permanently stamp him, even though his disorder may have been of comparatively brief duration and one from which he may have made complete recovery.

26. The avoidance of an undesired stigma, by allowing less formal arrangements for suitable cases, is much to be desired, but it must always be borne in mind that the associations springing from any arrangement will depend in the long run upon the actual facts and usage and not upon any verbal description or sympathetic intention. Escape from stigma is practically impossible where the stigma is justified by the facts.

#### TYPES OF PATIENTS TO BE DEALT WITH.

27. One difficulty in dealing with mental disorders is that they present so great a variety of conditions. Thus the most lasting and grave forms of mental unsoundness may at their onset present only a mild type of mental disturbance. On the other hand, some of the most acute forms may be of only temporary duration, almost sure to recover and possibly unlikely to recur. Then again some of the forms are marked by a natural tendency to remission and recurrence with intervals of apparent mental health; others, and these perhaps the most dangerous forms of mental

disorder, are very difficult to detect and are carefully concealed by the patient for long periods; there are also chronic forms which present no dangerous or conspicuously objectionable characters.

#### NEED FOR MORE FLEXIBILITY IN ARRANGEMENTS: PROPOSED PROVISIONAL ORDER.

28. It is clear that if the best possible is to be done for the patient as a sick person the facilities for treatment and the types of accommodation must be sufficiently various to suit the conditions defined in para. 27.

29. Another reason for urging the need of flexibility is the frequent difficulty and uncertainty of diagnosis and prognosis, and the claim for fuller opportunities for research if treatment is to be placed on a more secure basis.

30. There is already a procedure by Urgency Order provided for in the Act, and in practice a large proportion, approximating to 60 per cent. in some institutions, of the private patients admitted to institutions are admitted in the first instance on this Order, on the ground that it is expedient for the welfare of the patient that he should be forthwith placed under care and treatment.

31. The Order in this case is made, not by a judicial authority, but by someone closely related to the patient. Some such power is essential to enable immediate steps to be taken when delay would be dangerous or harmful, but it would be sufficient for safety and convenience that the duration of such an Order should be, say, “three days,” for clearly it is desirable that at the earliest possible moment there should be judicial authority for a measure which means the loss of personal liberty.

32. It would, however, be a great advantage to the patient that such an Order should be capable of extension, on the approval of a judicial authority, for a further twenty-eight days. This would provide opportunity for observation and possible recovery before submitting a petition for a formal Reception Order, and there is reason to believe that in many cases a Reception Order would then not be necessary.

33. If this plan were adopted it would appear best to call such an Order a Provisional Order, and that such Order should supersede the present Urgency Order. The exact form which it is suggested this Provisional Order and the accompanying papers should take is appended hereto (vide Appendix B).

34. The Provisional Order made by a relative, or where necessary by a Relieving Officer, would expire automatically at the end of three days, unless it were endorsed by a judicial authority whereby its validity would be continued for a further period of twenty-eight days. Wherever possible this Order should be signed by the judicial authority prior to the admission of the patient and in no case later than three days after admission. At the expiration of a Provisional Order the patient must be discharged unless he is either placed under a Reception Order or becomes a voluntary boarder.

35. In support of this proposal it may be pointed out that in the existing provisions for so-called “pauper patients” there is opportunity for a period of observation of seventeen days before a formal Reception Order is made, and there is evidence from experienced medical practitioners that a number of patients who come under observation in this way get well and go home before this period has elapsed, without a Reception Order having been made.

#### VOLUNTARY BOARDERS.

36. The Association advises that the provision enabling registered hospitals and licensed houses to receive suitable patients as voluntary boarders should be extended, under suitable conditions, to the county and county borough asylums. In each individual case the arrangement would require the approval of the Medical Superintendent or his deputy.

37. The advantages of the voluntary boarder system are that it is subject to the consent of the patient and provides for his care and treatment for so long as this may be necessary; in addition, it avoids or postpones the necessity for a Reception Order. It is valuable, too, as a transition measure when the patient is recovering from his illness and discharge from the Reception Order is justifiable but the

patient still requires treatment. The use of this system has steadily increased in recent years, many patients being now received as voluntary boarders who formerly would have been dealt with under a Reception Order.

38. A condition of the present procedure, whereby the reception of a voluntary boarder into a licensed house has to depend on permission being obtained beforehand from the Board of Control, or in the case of a registered hospital from two members of the Visiting Committee, appears unnecessary, although it is fully recognized that the present form of notification and report on voluntary boarders should be maintained.

39. In the interest of the patient it is desirable that the notice to leave should be extended to seventy-two hours.

#### TEMPORARY BOARDERS.

40. The Mental Treatment Bill of 1923 introduced a new proposal—namely, the temporary treatment of mental disorder without a Reception Order under the Lunacy Acts in an approved institution on the recommendation of a medical practitioner, subject to the consent of the patient or to his being incapable of volition. The period of treatment is limited to six months, subject to the power to extend the treatment for a further six months when recovery within that period is reasonably probable.

41. The institutions which may be approved under this Bill include, in addition to institutions under the Lunacy Act, hospitals or parts of hospitals outside the Lunacy Acts, and institutions that may hereafter be established by Visiting Committees. For admission thereto the recommendation of the doctor declares that the patient shows symptoms of mental disorder.

42. There is in the Bill no definition of the term "mental disorder," but presumably it is intended to be used in the sense already defined in this document and to include both persons of "unsound mind" and the "mentallyailing."

If this is so it would enable acute cases and others which are likely to be brief in duration to be received and detained without the formality of a Reception Order, not only in the institutions at present recognized under the Lunacy Act but also in ordinary hospitals not so recognized.

43. The Association finds itself in agreement with this proposal, at least so far as it goes. It is necessary, however, to point out that although the Mental Treatment Bill is based on the consent of the patient (and even extends to the case where the patient is incapable of volition) and applies to institutions managed by a Visiting Committee, it does not effect the same result as would come about from extending the voluntary boarder principle to the county and county borough asylums. If this were done, and if the Provisional Order which is suggested above were available, there would appear to be no special object in applying the provisions of the Mental Treatment Bill to the existing institutions. The voluntary boarder principle might easily be made to cover all the consenting cases and it would in fact go further, in that it is indefinite in its duration and is applicable not only during the first six or twelve months of treatment but also during convalescence if so desired, and in these respects the proposals in the Bill would not be an adequate substitute.

44. The application of the provisions of the Bill to include patients for the time being incapable of volition is a valuable provision, as it includes cases which would not otherwise gain the advantage of these temporary arrangements, although they might be provided for under the Provisional Order as suggested in paras. 30-34.

45. In the Mental Treatment Bill the expression "incapable of volition" is used to describe certain patients who may come under its provisions. This expression, in practice, will not always be easy of interpretation, and it is suggested that the actual facts on which judgement of the incapacity must be based—namely, that the patient does not, when given the choice, exercise it—would be preferable as the basis of the definition. It is therefore suggested that Section 4 (1) (a) of the Bill should be modified to read somewhat as follows:

"(a) A recommendation for treatment shall only be given under this section in respect of a person who either is willing to submit to treatment or does not

express unwillingness to submit to treatment, or in whose case, if he is a minor, consent to his reception as a patient has been given by his parent or guardian, and every such recommendation shall state whether the person in respect of whom it is given is willing to submit to treatment or does not express unwillingness to submit to treatment or is a minor on whose behalf the necessary consent by his guardians has been given, as the case may be";

and that Section 4 (5) be amended to read somewhat as follows:

"(5) Where the person to be received as a patient has not definitely expressed his willingness to be received or is a minor, there must be annexed to the recommendation for treatment a statement signed by a justice of the peace to the effect set out in Part II of the Schedule to this Act."

If in fact the patient resists being dealt with under this provision he cannot enjoy its advantages and must be dealt with otherwise.

46. The proposal to recognize non-registered hospitals for the reception and temporary treatment of cases of mental disorder is one that the medical profession welcomes on the ground that it will be valuable for purposes of education and research and will tend to link up the study of mental disorders with general medicine. It will undoubtedly be welcomed also by many patients.

47. The Association is of opinion that in addition to the institutions recognized in the Mental Treatment Bill there should be the power to approve under this Bill: (a) houses which are supported wholly or partly by voluntary contributions or which are privately owned, for the reception of patients under the provisions of the Bill; and (b) the reception as single patients under the Bill in houses not so approved, provided that a medical practitioner gives a written recommendation in each case, stating that suitable treatment can be obtained for the patient in the proposed house.

48. It is urged that the principle of permitting "after-care" homes and convalescent homes at the seaside or elsewhere in connexion with county and county borough mental hospitals should be recognized.

49. It should be possible upon the Order of the petitioner, without the consent of the Board of Control being first obtained, to remove a patient detained under Order in his own house or in "single care" to an institution if and when the mental condition of the patient renders this course advisable; the fact of removal in any such case to be reported to the Commissioners. Similar powers already exist for the committee of the person in "lunatics so found."

50. Reference has already been made in paragraph 40 to the fact that cases of mental disorder may lawfully be received if they are not "lunatics" or "alleged lunatics." Whether or not it is proper to receive, outside the Act, a patient who is suffering from mental disorder, is not always an easy question to decide, and a mistake on the part of the person receiving such a patient may result in a prosecution.

51. It is possible that institutions under Visiting Committees may come to include what have been described as clinics both with beds and with consultative arrangements for out-patients on lines comparable to venereal disease clinics. It is hardly likely that these would be established except in large centres of population where there is no ordinary hospital provision for these cases.

The development of centres of this type would be of assistance for the purpose of getting expert opinion for certification and other purposes, and might well take the place of the receiving wards of workhouses for the reception of patients in the first instance.

#### VALUE OF VARIETY IN TYPE OF INSTITUTIONS.

52. That the variety of provision which at present exists for the treatment of patients should be continued seems very much to be desired. There are facilities for private patients on various scales in the licensed houses, registered hospitals, and publicly maintained institutions, or under single care. Patients needing assistance from public sources

or from charitable foundations are provided for in the public institutions and in the registered hospitals.

53. Some sections of the population prefer public management, some private. Each type of institution has a good record of work done and of trustworthy management under official supervision.

54. The Association is satisfied that there exists a desire in the community generally that many patients should be able to be treated otherwise than in public institutions, and should the existing veto on the setting up of new licensed houses or the extension of existing licensed houses result in the diminution or inadequacy of this provision it may be necessary to repeal this veto or to provide extended facilities for the treatment of patients in small numbers in private hands under proper safeguards. The opinion of practitioners in general practice in various parts of the country has been sought on this point, and the unanimously expressed opinion is in favour of the continuance of such provision, as meeting the wishes both of patients and of patients' friends.

55. The scheme contained in Appendix C shows the grouping of patients suffering from mental disorders from the point of view of the administrative measures possible for dealing with them and for bringing them under treatment in accordance with the foregoing suggestions.

#### CERTIFICATION.

56. When care and control are deemed necessary and the various methods of securing treatment by voluntary consent are not available an Order of some kind becomes necessary, whether it be the proposed Provisional Order, or the full Reception Order, a Detention Order, or an Urgency Order.

In all these cases the Order must be justified by evidence, and this must of course include medical evidence in the form of a certificate or certificates.

57. It has become customary to speak of "certification" as being the fact which deprives a patient of his freedom, whereas of course the formal authority is in all cases the Order, and this is made not by the certifying doctor but by the judicial authority or, in the case of the Urgency Order, by a relative. Therefore whenever a person is medically examined it should be understood that the fee paid to the examining medical practitioner is for the fact of having conducted the medical examination and not for having certified the patient as insane.

58. While it is desired to guard against the elevation of the medical certificate to a position of authority which it does not possess, there is no wish to underestimate the great importance of the certificate as evidence.

Indeed it is desired to insist upon its being given very definitely the status of evidence; and therefore, that the protection which witnesses in courts of law are entitled to receive shall be extended to the practitioner who signs a certificate under the Lunacy Acts. (Vide Appendix A.)

59. It is recognized that the function of the medical practitioner does not intrude on the power of the magistrate. The doctor simply contributes to the evidence on which the magistrate bases his judicial decision, acting as the representative of the law.

It is in harmony with this view that the Association, while not wishing to dictate the duties to be laid upon the magistrate, favours his interviewing the patient, so that the patient may present his view of the position. Incidentally, this would have the additional advantage of rendering unnecessary the presentation to the patient, after his admission, of the form notifying his right to see a magistrate.

60. In these proposals the Association aims to secure that there shall be judicial authority for detention, the only exception being during the first three days, when it may be unavoidable that the onus should be placed upon a relative, or on a Poor Law officer. (Vide paras. 31-34.)

61. It is in accordance with the principle of placing the real responsibility where it properly rests—viz., on the judicial authority who makes the Order—that it is suggested that the duration of the Urgency Order or Provisional Order should in the first instance, when it is for reasons of avoiding delay made by a near relative, only be valid for three days instead of for a week as at present.

62. A question has been raised as to the qualifications that should be required of the judicial authority. All that the Association feels entitled to say on this point is that it is essential to the welfare of the patient as well as to the convenience of the medical practitioner that access to the judicial authority qualified to sign the Reception Order should be near at hand and readily obtained.

63. With regard to Section 43 of the Lunacy Act and Form 8 thereof, while it is considered that one of the medical practitioners signing the medical certificate should, whenever practicable, be the usual medical attendant of the patient, this condition should be abrogated in those "single case" cases where it is intended that the usual medical attendant should continue to be the "medical attendant" of the patient.

64. The certificate of a doctor in principle consists of three elements—namely:

(i) Observations by the doctor himself, at the time of examination, of conduct or behaviour of an abnormal kind (using the term conduct in a wide sense to include all modes of self-expression). These observations may be supported by other observations made on previous occasions and by observations reported by other persons (whose names are given);

(ii) The conclusion that such behaviour is due to mental disorder; and

(iii) The further conclusion that the mental disorder is of such a nature or degree that the patient is a proper person to be taken charge of and detained for care and treatment.

65. The Association does not support the suggestion that second certificates should be signed by specially approved practitioners.

#### SUGGESTED AMENDMENT OF CERTIFICATES AND FORMS.

66. The actual form and wording of the Petition, Statement of Particulars, Certificates, and Reception Order require amendment:

(a) It is suggested that the terms "lunatic" and "idiot" should be omitted throughout and that in place thereof the phrase "a person of unsound mind" should be used. Even the phrase "alleged to be of unsound mind" should be omitted, except where its use is essential;

(b) It is proposed to alter the Statement of Particulars in the following respects:

(i) To substitute "whether previous history of mental disorder" for "whether first attack";

(ii) To substitute "Age at onset of mental disorder" for "Age on first attack";

(iii) To substitute "When and where previously under treatment for mental disorder" for "When and where previously under care and treatment as a lunatic, idiot, or person of unsound mind"; and

(iv) To substitute "Duration of present illness" for "Duration of existing attack."

67. In the certificate (Form 8) it is suggested that:

In para. 2 "separately from any other practitioner" be deleted. This would be following the proposal in the Mental Treatment Bill and would facilitate the formation of a sound and well grounded opinion. Evidence of mental unsoundness is sometimes difficult to elicit and a joint examination would spare the patient undue annoyance.

3 (a) should read: "Facts pointing to this conclusion observed by myself at the time of examination, viz.:"

3 (b) should read: "Facts observed by myself on previous occasions."

3 (c) should read: "Statements communicated by others."

68. The Reception Order might be more explicit and correspond more closely with the medical certificates thus:

"I authorize you to receive, take into your charge, and detain A.B., etc."

69. There is some uncertainty at present as to the right of the medical officer or medical attendant to administer medical treatment to a patient under a Reception Order, against the patient's wishes, even though the friends approve of the treatment proposed; this uncertainty should be cleared up.

#### PROTECTION OF PATIENTS.

70. After a careful consideration of the subject, the Association is firmly of opinion that the obstacles to the improper reception or detention of patients in institutions under the Lunacy Acts are such as to render improper reception or detention practically impossible, and the evidence received from medical practitioners resident in various quarters is unanimous that such cases do not in practice arise (vide Appendix D).

From the evidence which the Association has received it would appear that so far from there being any risk of patients being detained too long in institutions (as has been alleged) the risk is rather that, owing largely to pressure from patients' relatives and friends, discharge may sometimes be premature.

#### POOR LAW PATIENTS.

71. Subjoined are a number of recommendations for amendment of the law affecting Poor Law infirmaries and so-called "pauper patients":

- (a) "Observation wards" for mental cases should be in a separate infirmary or Poor Law hospital and not in the workhouse.
- (b) A medical officer should not have the power given him by Section 24 of the Lunacy Acts to detain a patient for fourteen days "against his will" without the authority of a justice.
- (c) It should be made clear in any future legislation that the institutions for lunatics referred to in Section 16 of the Lunacy Act 1890 include a Poor Law Infirmary or hospital. This would enable many cases of senile dementia, which at present have to be sent to the county or county borough asylums, to receive treatment in the wards of Poor Law infirmaries or hospitals.
- (d) While no general statement can be made as to the suitability of Poor Law workhouses for the reception of patients of unsound mind (the accommodation provided in such institutions varying widely) the continued detention of patients in these institutions is to be deprecated.

(e) The provision of clinics or reception houses in places where they would be convenient, or of better accommodation in workhouse infirmaries, would avoid the necessity of placing patients in unsuitable companionship as now apparently happens in the "insane" wards of the workhouses.

(f) It is unfortunate that patients with "mental disorders" should have to invoke the machinery of the Poor Law in order to obtain treatment, and the avoidance of this procedure could be secured by the direct admission of patients to recognized mental hospitals.

(g) For removal to an asylum of a so-called "pauper patient" only one medical certificate is at present required (except in the case of patients dealt with under Section 13 of the Lunacy Act 1890). Whether the procedure of certification is made uniform for all patients or not, the Association considers that two medical certificates should be required by law in all cases.

#### MISCELLANEOUS.

72. Bona-fide communications to constables, relieving officers, or overseers initiating proceedings under Sections 13 (i), 15 (i), and 20 of the Lunacy Act 1890 should be privileged.

73. The right to see a magistrate is accorded to all patients placed under Order except those dealt with under Section 13 of the Lunacy Act 1890, and this is an anomaly which should be removed.

74. In the interests of the patients, the classification of patients suffering from various mental disorders should, as far as possible, be effected, and this with as little delay as possible.

75. It is urged that no person not charged with an offence

against the law should be examined with regard to the state of his mind in a public court, as is at present allowed, and is, as a matter of fact, sometimes done.

76. Powers of forcible entry in order to visit, examine, or remove a person who is deemed to be of "unsound mind" should be granted to magistrates in connexion with cases arising under Sections 13 (2) and 20 of the Lunacy Act 1890.

#### TYPES OF ACCOMMODATION FOR PATIENTS SUFFERING FROM MENTAL DISORDER.

77. The following types of accommodation for persons suffering from mental disorder are suggested:

- (i) Non-registered hospitals or parts of or adjuncts to hospitals, voluntary or Poor Law.
- (ii) Institutions or Clinics or Homes established, or to be established, by Local Authorities.
- (iii) Homes to be founded on a charitable or semi-charitable foundation.
- (iv) Recognized homes on a purely private basis for several patients.
- (v) Publicly maintained mental hospitals and specialized wards of Poor Law hospitals.
- (vi) Registered mental hospitals.
- (vii) Private (licensed) mental hospitals, and the approved annexes of (v), (vi), and (vii).
- (viii) Private houses for single patients.

Asylums.

#### CLASSIFICATION AND ALLOCATION OF PATIENTS.

78. For those who are of "unsound mind" and for whom measures of control have become desirable it should be open to adopt various methods of procedure:

- (a) Voluntary—
  - (a) by the patient's act,
  - (b) by the action of a friend or relative where the patient does not refuse or where he is a minor.
- (n) Compulsory by the action of a relative or relative officer—
  - (a) as a temporary or provisional measure for three days,
  - (b) as a temporary or provisional measure for a month with the approval of a judicial authority.
  - (c) Compulsory by the order of a judicial authority under the Reception Order.

"Compulsory (c)" patients of unsound mind may be received in (v), (vi), (vii), and (viii).  
 "Compulsory (b)" patients may be received in (i), (ii), (iii), (iv), (v), (vi), (vii), and (viii).  
 "Voluntary (a)" patients of unsound mind may be received in (v), (vi), (vii), and (viii), and also in (i), (ii), (iii), and (iv).

The "mentally ailing" but not of unsound mind may be received in (i), (ii), (iii), (iv), and (viii), and as voluntary boarders with the approval of the medical superintendent in (v), (vi), and (vii).

#### APPENDIX A.

#### CONSIDERATIONS WHICH SUPPORT THE CLAIM THAT THE CERTIFYING PRACTITIONER SHOULD ENJOY THE IMMUNITIES OF A WITNESS.

NOTE.—The quotations are from the Lunacy Act 1890, the italics being introduced for purposes of emphasis.

1. Section 4. Sub-section (1).  
A person shall not be received or detained as a lunatic, etc., "unless under a reception order made by a Judicial Authority."
2. Section 9. Sub-section (2).  
"Judicial Authority shall . . . have the same jurisdiction and power as regards summoning and examination of witnesses, the administration of oaths, and otherwise, as if he were acting in the exercise of his ordinary jurisdiction."
3. Section 28. Sub-section (4).  
"Every medical certificate made under and for the purpose of this Act shall be evidence of the facts therein appearing and of the judgement therein stated to have been formed by the certifying medical practitioners on such facts, as if the matters therein appearing had been verified on oath."

4. If the Judicial Authority signs a Reception Order without personally seeing the patient the M.O. of the institution must inform the patient that he has the right to claim an audience with some other Judicial Authority, who after such audience must report to the Commissioners in order that these "may take such steps as may be necessary to give effect to the report." Section 8 (3). Should the M.O. think that such an audience might be prejudicial to the patient he will not tell the patient of its possibility, but he must certify his opinion to the Commissioners. Section 8 (1).

NOTE.—The Powers of the Judicial Authority to visit the patient to make various inquiries, to summon other witnesses (Section 6) to administer oaths (Section 9 (21)) show that medical certificates are not per se conclusive, that is, the certificates are evidence, not judgement.

5. Further, when an alleged lunatic demands a jury in the case of an "inquisition" the Judge by personal examination may decide whether the alleged lunatic is mentally competent to form and express a wish for a jury (Section 91).

6. Again, without a jury, the "Masters" (barristers) shall "personally examine the alleged lunatic and take such evidence as they think fit in order to ascertain whether he is of sound mind or not." Section 92.

7. Where the Masters certify in one direction or the other the certificate shall have the same effect as an inquisition taken upon the oath of a jury. Section 93.

NOTE.—The above rules and practices show that the principle accepted in the Lunacy Act is that the responsibility for detaining a person to be (or not to be) of unsound mind rests with an appropriate legal officer and not with a member (or members) of the medical profession. These may, as may other persons, give evidence, and this evidence (in whole or in part) must be in the form of a prescribed certificate. It is for the duty constituted Judicial Authority to consider the medical certificates together with any other evidence he may think advisable, and after consideration to give his decision. Upon this decision the whole of the future action relative to the patient depends. In a word, the medical practitioner gives evidence; the Judicial Authority pronounces judgement; the medical practitioner is a witness; the Judicial Authority is a judge. Hence the claim by the practitioner for the immunities of a witness is strictly in accord with the whole tenor of the Lunacy Act.

## APPENDIX B.

### PROPOSED PROVISIONAL ORDER FOR DETENTION.

I, the undersigned, .....  
being a Justice of the Peace for .....  
having visited (a) .....  
do hereby authori-  
ment for a period  
date.

DATED this, ..... day of, ..... 192 .

Signed, .....  
A Justice of the Peace for  
(or as the case may be.)

To the Medical Superintendent,

..... Hospital,  
Recognized Home  
(or as the case may be.)

N.B.—Wherever possible this Order should be signed prior to the admission of the Patient and in no case later than 3 days after admission.

(a) Name of Patient.

### FORM OF PROVISIONAL ORDER

FOR THE RECEIPT OF A PATIENT, WITH MEDICAL CERTIFICATE  
AND STATEMENT ACCOMPANYING PROVISIONAL ORDER.

I, the undersigned, being a Person Twenty-one years of age,  
hereby authorize you to receive (a) .....  
as a Patient into your Hospital, etc.  
for observation, care, and treatment, whom I last saw at .....  
day of ..... 192 .

I am not related to or connected with the Person signing the  
Certificate which accompanies this Order in any of the ways  
mentioned in the Margin (b). Subjoined hereto is a Statement  
of Particulars relating to the said (a) .....

SIGNED, .....  
Name and Christian }  
Name at length }  
Rank, Profession, or }  
Occupation (if any) }

## APPENDIX C.

### Scheme for Classification of Patients suffering from Mental Disorders.

## Current Notes.

## APPENDIX D.

## PROTECTION OF ALLEGED LUNATIC.

- (NOTE: The references are to the Lunacy Act 1890.)
1. Judicial Authority may decide to see patient and may postpone decision to secure this. Section 6 (1).
  2. In the meantime may make inquiries of or concerning the lunatic, and may visit him. Section 6 (1) (2).
  3. At hearing may have lunatic, and person appointed by lunatic, present. Section 6 (3).
  4. May adjourn for fourteen days, and may at continued hearing summon any person to attend before him. Section 6 (4).
  5. All persons bound to secrecy save lunatic and his friend. Section 6 (5).
  6. Judicial Authority may put witnesses on oath. Section 9 (2).
  7. Where Petition granted forthwith and patient not seen by Judicial Authority, the medical officer (institution) must within twenty-four hours inform him in writing of his right to see or be seen by a Judicial Authority other than the one who has granted the Petition. If the M.O., however, thinks that such a visit would be prejudicial to the patient he will not tell the patient of this right, but he must certify his opinion to the Commissioners. Section 6 (1).
  8. The Judicial Authority who sees the patient on the claim under No. 7 shall be entitled to see all the papers in the case and shall send to the Commissioners a report, and "the Commissioners shall take such steps as may be necessary to give effect to the report." Section 8 (3).
  9. The M.O. one month after reception of patient shall send to the Commissioners (and to the Visitors) a report as to the mental and bodily condition of the patient. After reception of this report one or more of the Commissioners shall visit the patient and shall report whether the detention of the patient is or is not proper (Section 39 (2) and (3)). Similarly one or more of the Visitors will visit the patient and if in doubt as to the propriety of his detention will report to the Commissioners who must make all necessary inquiries. Section 39 (4).
  10. If the Commissioners in any case under this Section 39 determine that a patient ought to be discharged, they may make an order for his discharge.
  11. Letters by patients to Lord Chancellor, Commissioners, etc., must be forwarded unopened; and notices to this effect must be posted in the institution; also of right of patient to request personal and private interview with a Commissioner or Visitor. Section 42 (1).
  12. A medical practitioner who has signed a certificate for the reception order in the case of a private patient shall not be the regular professional attendant of the patient while detained under the order. Section 43 (1).
  13. Any Commissioner or Visitor may give an order for patient to be visited by any relation or friend, or by any medical or other person whom any relation or friend desires to be admitted to him. If any manager or officer prevents or obstructs such admission he is liable to a penalty not exceeding £20. Section 47 (1), (3).

## British Medical Association.

## CURRENT NOTES.

## Hospital Policy.

THE British Medical Association has just issued (price 3d.; 3½d. post free) a pamphlet embodying its policy as affecting hospitals, together with an introductory note. This policy deals with the following matters:

1. Inter-relationship and co-ordination of hospital provision.
2. Utilization of municipal hospitals for civil needs.
3. Utilization of Poor Law hospitals for civil needs.
4. Voluntary hospital policy (Great Britain and Ireland).
5. Voluntary schemes.
6. Contributory schemes for "private" patients.
7. Standards for hospitals (England and Wales) with 100 or more beds.
8. Scheme for formation of local hospitals committees.
9. Subscribers' letters.

The decisions enunciated in the pamphlet have been arrived at after conferences between members of the medical staffs of voluntary hospitals, correspondence with hospitals, meetings of hospital staffs, and discussions with medical practitioners throughout Great Britain and Ireland, and have received the approval of the Representative Body of the Association.

## Association Prizes for Essays by Medical Students.

The Council of the Association will award in March, 1925, prizes of £10 each, for the best essays on the diagnosis and treatment of chronic intestinal obstruction. One prize is open to competition by the final-year medical students in each of the following groups of schools:

- Group 1.—University of Aberdeen; University of St. Andrews (University College, Dundee).
- Group 2.—Queen's University of Belfast; University of Dublin (University College, Dundee).
- Group 3.—University of Birmingham; University of Bristol; University of Cambridge; University of Edinburgh; University of Glasgow; University of London; University of Manchester; University of Oxford; University of Sheffield; University of Southampton; University of St. Thomas; University of Toronto; University of Wales; University of York.

College, Cork; University College, Dublin; University College, Galway; Royal College of Surgeons in Ireland (Schools of Surgery); University of Birmingham; University of Bristol; University of Cambridge; University of Edinburgh; University of Glasgow; University of London; University of Manchester; University of Oxford; University of Sheffield; University of Southampton; University of St. Thomas; University of Toronto; University of Wales; University of York.

The prizes will be awarded to the authors of the best essays sent in from the respective groups; but if no essay is deemed worthy of a prize, no prize will be awarded in that group. The essays, not exceeding 5,000 words, should be clinical, and must include concise notes of three cases personally observed. Essays should be plainly written on foolscap paper (one side only), and must reach the Medical Secretary, British Medical Association, 429, Strand, W.C.2, not later than January 31st, 1925. Each essay must be signed by a pseudonym; it must be accompanied by a sealed envelope marked outside with the pseudonym, and containing inside a signed and dated statement that the essay is the bona-fide work of the competitor, and that he or she has not yet passed the final professional examination, together with full name, address, and medical school. The following members of the Association have kindly undertaken to act as examiners: Sir H. Gilbert Barling, Bt., C.B. (Birmingham); the Rt. Hon. Lord Dawson of Penn, G.C.V.O., K.C.M.G. (London); Dr. W. E. Hume, C.M.G. (Newcastle-on-Tyne); Mr. H. Wade, C.M.G., D.S.O. (Edinburgh). The decision of the examiners will be final.

## Middlemore Prize, 1925.

The Middlemore Prize was founded by the late Richard Middlemore, F.R.C.S., of Birmingham, to be awarded for the best essay or work on any subject which the Council of the British Medical Association might from time to time select in any department of ophthalmic medicine or surgery. For many years the prize has been awarded to the author of the best essay received in connexion with the specific subject, but it has been decided on this occasion to deal with the award of the prize on a broader basis. The Council will accordingly award the prize in the year 1925 to that person who is adjudged to have submitted to the Association the best contribution published or not, provided that the contribution shall not have been published or prepared more than three years prior to the date on which applications are receivable in competition for the prize. The prize will take the form of an illuminated certificate and a cheque for £50. Contributions in competition for the prize must reach the Medical Secretary, British Medical Association, 429, Strand, W.C.2, on or before Monday, February 2nd, 1925. The contributions will be judged by examiners appointed by the Association, and the decision of the Council will be final.

## The Half-Yearly Indexes.

The usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPILOGUE have been prepared and will be published shortly; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Those wishing to receive the indexes regularly as published should intimate this desire.

## Association Notices.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BATH AND BRISTOL BRANCH.**—A clinical meeting of the Bath and Bristol Branch will be held at Bristol on Wednesday, January 22th.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A meeting of the Nuneaton and Tamworth Division will be held at the Tamworth General Hospital on Thursday, January 22nd, when Dr. K. D. Wilkinson will speak on cardiac irregularity.

**BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.**—A meeting of the Division will be held on Thursday, January 22nd, in the Royal Infirmary, Dumfries, at 3.30 p.m. Business: Annual report; ambulance lectures; programme for 1925; draft Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance.

**ESSEX BRANCH: MID-ESSEX DIVISION.**—A meeting open to all practitioners in the Division will be held at the address of the Honorary Secretary (Littleton Hall, Bynalwood, Essex) on Sunday, January 18th, at 3.15 p.m., to discuss the draft evidence to be presented to the Royal Commission on National Health Insurance, and to elect two representatives to confer with the Essex Panel Committee.

**FIFE BRANCH.**—A general meeting of practitioners arranged by the Fife Branch and the Fife County Panel and Local Medical Committees will be held in the Station Hotel, Kirkcaldy, on Thursday, January 22nd, at 3 p.m., to consider the draft evidence which it is proposed to put before the Royal Commission on National Health Insurance on behalf of the British Medical Association. The draft evidence was printed in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 3rd.

**KENT BRANCH: BROMLEY DIVISION.**—A meeting of all medical practitioners in the Division will be held at the United Services Club, London Road, Bromley, to-day (Friday, January 16th), at 8.30 p.m., to consider the draft Memorandum of Evidence which is to be submitted to the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. G. C. Anderson, Deputy Medical Secretary, who will also answer any questions.

**KENT BRANCH: DARTFORD DIVISION.**—A special general meeting, called by the Dartford Division, will be held at the Livingstone Hospital, Dartford, on Tuesday, January 27th, at 3 p.m. Business: To consider the draft evidence to be put before the Royal Commission by the British Medical Association (see BRITISH MEDICAL JOURNAL SUPPLEMENT, January 3rd); to arrange date of a clinical meeting. All practitioners in the district are asked to make an effort to attend the meeting.

**LANCASHIRE AND CHESHIRE BRANCH: BURY DIVISION.**—A special combined meeting of the Bury Panel Committee and the Bury Division of the British Medical Association will be held in the Derby Hotel on Wednesday, January 21st, at 8.30 p.m., to consider and discuss the draft Memorandum of Evidence to the Royal Commission on National Health Insurance. Those attending are urged to bring with them the SUPPLEMENT of January 3rd, which contains the whole matter, and to study it beforehand.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—The Hyde Division is holding a supper d'ansant at Oaklands, Mottram New Road, Hyde, on Friday, January 23rd, at 8.30 p.m.

**LANCASHIRE AND CHESHIRE BRANCH: LIVERPOOL DIVISION.**—A meeting of practitioners in the area of the Liverpool Division will be held at the Medical Institution, 114, Mount Pleasant, Liverpool, on Wednesday, January 21st, at 3 p.m., when Dr. G. C. Anderson, Deputy Medical Secretary, will open a discussion on the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance.

**LANCASHIRE AND CHESHIRE BRANCH: MID-CHESHIRE DIVISION.**—A British Medical Association lecture will be given to-day (Friday, January 16th), at 8.45 p.m., in the Board Room of the Altrincham General Hospital, by Dr. S. A. Kinnier Wilson (London) on Neuritis and Neurasthenia. Members of neighbouring Divisions are heartily welcome.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—The following meetings will be held in the City Division area in order to give members and non-members of the Association resident in the area an opportunity of discussing fully the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance. (1) Tuesday, January 20th, at 9.30 p.m., at West Public Library, Thornhill Square, Islington. Speaker: Dr. G. C. Anderson, Deputy Medical Secretary, on, opposite Shoreditch Railway Station, and Mr. E. B. Turner, F.R.C.S. It is concerned will attend at least one of the

meetings, and also carefully study the SUPPLEMENT, BRITISH MEDICAL JOURNAL, of January 3rd. Any medical practitioner who has not received a copy can obtain one by applying to the Secretary, Dr. Ernest A. Worley, 43, De Beauvoir Road, N.1. A meeting of the Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, February 10th, at 9.30 p.m., when Dr. Edwin Smith, coroner for North-East London, will read a paper on some legal relationships of the practitioner.

**METROPOLITAN COUNTIES BRANCH: FINCHLEY DIVISION.**—A meeting of the Finchley Division will be held at the Finchley Memorial Hospital on Tuesday, January 20th, at 8.45 p.m. All medical prac-

tioners within the area are invited to attend to discuss the Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance.

**METROPOLITAN COUNTIES BRANCH: HAMSTEAD DIVISION.**—A meeting of the Hampstead Division will be held at the Hampstead Town Hall, Haverstock Hill, on Thursday, January 22nd, at 8.30 p.m., to consider the draft Memorandum of Evidence proposed to be placed before the Royal Commission by the British Medical Association. The meeting is open to non-members. The attendance of medical practitioners is earnestly requested, and they are asked to read carefully beforehand the draft Memorandum and the questions enumerated on page 9 of the SUPPLEMENT of January 3rd, to which answers will be formulated at the meeting.

**METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.**—A meeting of the Kensington Division will be held at the Kensington Town Hall at 3.30 p.m. on Friday, January 23rd, to discuss the evidence it is proposed to place before the Royal Commission on National Health Insurance. It is hoped that all medical men in the Divisional area, whether members of the Association or not, will attend and express their views, as the matters under discussion will affect all practitioners in whatever class of work they are engaged.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—A meeting of the Lewisham Division will be held at the Parish Room, St. Laurence Vicarage, Bromley Road, Catford, S.E.6, on Tuesday, January 20th, at 8.45 p.m., under the chairmanship of Dr. A. Beattie. Mr. Archer Ryland will read a paper on danger signals in the acute mastoid, illustrated by lantern slides.

**METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.**—A meeting of the South Middlesex Division will be held at St. John's Hospital, Twickenham, on Wednesday, January 21st, at 8.15 p.m. A discussion on scarlet fever from a public health point of view will be opened by Dr. H. A. Günther.

**METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.**—A meeting open to all practitioners in the Division will be held on Tuesday, January 20th, at the Wesleyan Church School Rooms (near Leyton Station, Midland Railway) at 3.30 p.m., for the purpose of considering the draft Memorandum of Evidence to be presented to the Royal Commission on National Health Insurance (BRITISH MEDICAL JOURNAL SUPPLEMENT, January 3rd). Dr. Alfred Cox, Medical Secretary, will attend and answer any questions that may be asked.

**METROPOLITAN COUNTIES BRANCH: WEST HERTFORDSHIRE DIVISION.**—A meeting of the West Hertfordshire Division will be held in the Abbey Institute, Romeland, St. Albans, on Sunday, January 18th, at 2.30 p.m., for the discussion of the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. The subjects to be discussed include the question of including in the insurance scheme the dependants of all insured persons. As this would mean an enormous increase in the amount of insurance work to be undertaken by the general practitioner, it is a matter requiring very careful consideration. All medical practitioners in the area of the Division, whether members of the Association or not, are cordially invited to attend.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A meeting of the Willesden Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, January 21st, at 9 p.m., to consider the draft evidence to be submitted to the Royal Commission on National Health Insurance. In preparation for this meeting members and non-members of the Association are requested to attend an important meeting of all practitioners in Middlesex to be held at the Portman Rooms, Baker Street, W.1, on Sunday, January 18th, at 3 p.m., when Dr. H. B. Brackenbury will speak.

**METROPOLITAN COUNTIES BRANCH: WOOLWICH DIVISION.**—A meeting of the Woolwich Division, to which all practitioners are invited, will be held on Tuesday, January 20th, at 8.30 p.m., at the Shakespeare Hotel, Powis Street, Woolwich, to discuss the draft of the evidence to be given before the Royal Commission on National Health Insurance. The meeting will be preceded by a simple supper, at 2s. 6d. a head, at 8.30 punctually. Those intending to be present are asked to notify the honorary secretary (Dr. F. J. O. Blackmore, 138, Herbert Road, Woolwich, S.E.18) as early as possible.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—The annual dinner of the Chesterfield Division will be held at the Station Hotel on Wednesday, January 21st, at 7.30 p.m., when Dr. Brackenbury will give an address.

**MIDLAND BRANCH: DERBY DIVISION.**—A meeting, to which the whole of the medical profession (both members and non-members of the British Medical Association) in the Derbyshire Divisional Area are invited, will be held in the Board Room of the Derbyshire Royal Infirmary, on Friday, January 23rd, at 3 p.m., to consider the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. G. C. Anderson and Sir Richard Luce, M.P. At the close an opportunity will be given for the asking of questions. It is hoped that the meeting will be well attended in order that the voting on the questions to be submitted may be an expression of the general feeling of practitioners in the area.

**MIDLAND BRANCH: HOLLAND DIVISION.**—A joint meeting of the Holland Division and the Holland Panel Committee will be held at the White Hart Hotel, Spalding, to-day (Friday, January 16th), at 3 p.m., to consider the proposed evidence to be placed before the Royal Commission on National Health Insurance. Members are requested to bring the BRITISH MEDICAL JOURNAL SUPPLEMENT of January 3rd with them to the meeting.

**MIDLAND BRANCH: LEICESTER AND RUTLAND DIVISION.**—A meeting of the medical profession of Leicestershire and Rutland will be held in the dining room of the Oriental Café, Market Place, Leicester, on Thursday, January 22nd, at 3.30 p.m., for the purpose of discussing the draft Memorandum of Evidence which it is proposed to put before the Royal Commission on National Health Insurance.

**MIDLAND BRANCH: LINCOLN DIVISION.**—A meeting of the members of the medical profession resident in Lincoln (whether members of the British Medical Association or not) will be held at the offices of the Lincoln Insurance Committee, Palfrey Chambers, Silver Street (opposite Curtis and Maw's), to-day (Saturday, January 17th), at 8 p.m., to discuss the draft Memorandum of Evidence proposed to be placed before the Royal Commission, and to answer the questions which the Association is asking the medical profession on the subject.

**NORFOLK BRANCH: NORWICH DIVISION.**—A special meeting of the Norwich Division will be held in the Medical Library on Wednesday, January 21st, at 8.30 p.m., to consider the draft evidence to be placed before the Royal Commission on National Health Insurance. It is hoped that all medical practitioners in this area, whether members or not, will make every effort to attend and put forward their views.

**NORTH OF ENGLAND BRANCH: CLEVELAND DIVISION.**—Under the combined auspices of the Cleveland Division of the British Medical Association and of the Middlesbrough Panel Committee, a general meeting of the local medical profession will be held at Worsley House, North Ormsby Hospital, Middlesbrough, on Tuesday, January 20th, at 3 p.m., to discuss the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance, published in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 3rd, and to answer the series of questions contained therein. Afternoon tea will be provided by the hospital authorities at the close of the meeting.

**NORTH OF ENGLAND BRANCH: NEWCASTLE-UPON-TYNE DIVISION.**—Dr. William Brown, Wilde Reader in Mental Philosophy, Oxford, will give an address on psychotherapy at Armstrong College, on Tuesday, January 20th, at 5.30 p.m.—A meeting of practitioners in the area of the Newcastle-upon-Tyne Division will be held at the Medical Institute, 7, Windsor Terrace, on Tuesday, January 20th, at 8.30 p.m., to consider the evidence to be submitted by the profession to the Royal Commission on National Health Insurance, and a consensus of opinion will be taken on the different questions submitted, as set out in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 3rd. As this matter is of great importance to the profession generally and to those engaged in national health insurance work in particular, it is hoped that the meeting will be large and representative. Dr. R. A. Bolani, Chairman of the Council of the Association, who is also Chairman of the Committee appointed to collect the evidence, expects to be present.

**NORTH OF ENGLAND BRANCH: STOCKTON DIVISION.**—Two very important meetings will be held in the Stockton and Thornaby Hospital in connexion with the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance. All members and non-members are cordially invited, and it is hoped that there will be a large attendance at both meetings. At the first meeting, to be held on Wednesday, January 21st, at 4 p.m., Dr. Dix, the Representative for Group B on the Insurance Acts Committee, will address the meeting, and at the second meeting, to be held on Friday, January 23rd, at 8.30 p.m., the draft Memorandum will be discussed and reported upon.

**NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.**—A meeting called by the Sunderland Division and by the Sunderland Panel and Local Medical Committees will be held at 48, John Street, Sunderland, to-day (Friday, January 16th), at 8.30 p.m., and all practitioners in the Sunderland Division are invited to be present. The subject for consideration is the draft Memorandum of Evidence for the Royal Commission on National Health Insurance.

**NORTHERN COUNTIES OF SCOTLAND BRANCH.**—A meeting of the Northern Counties of Scotland Branch will be held at the Palace Hotel, Inverness, to-day (Friday, January 16th), at 6.30 p.m., when Professor Ashley Mackintosh (Aberdeen University) will deliver a British Medical Association lecture entitled "Neurological misgivings." The lecture will be followed by a dinner at 7.30 p.m.; it is hoped there will be a good attendance of members, both at the lecture and dinner. Members wishing to remain over the week-end should communicate with the manageress of the Palace Hotel.

**OXFORD AND READING BRANCH: OXFORD DIVISION.**—A meeting of the members of the medical profession of the district, arranged by the Oxford Division and Oxfordshire Panel Committee, will be held at the Radcliffe Infirmary, Oxford, on Wednesday, January 21st, at 3 p.m., to discuss the subjects contained in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 3rd.

**SOUTH MIDLAND BRANCH: BEDFORDSHIRE DIVISION.**—A general meeting of the Bedfordshire Division will be held at Emerson Norman's Restaurant, 9, High Street, Bedford, on Wednesday, January 21st, at 3 p.m. Agenda: Letter from British Legion regarding formation of a Medical Advisory Committee for Bedfordshire; to fill vacancy on Executive Committee. To be followed, the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance. All practitioners in the area are invited to attend the meeting. Tea will be provided.

**SOUTH MIDLAND BRANCH: BUCKINGHAMSHIRE DIVISION.**—A special joint meeting of the Bucks panel practitioners and the local members of the British Medical Association will be held at the Crown Hotel, Aylesbury, to-day (Friday, January 16th), at 3 p.m., to discuss the Memorandum of Evidence to be submitted to the Royal Commission. All practitioners in the area are invited. Any resolutions from this meeting will go to the Insurance Acts Committee and later to a Conference of Representatives in London. Therefore it is essential that all suggestions should be submitted as soon as possible. It is desired to emphasize before the Royal Commission the special difficulties under which country practitioners work, and the Secretary (Dr. T. Perrin, 10, Temple Square, Aylesbury) will be glad to receive any suggestions from rural practitioners.

**SOUTHEAST BRANCH: ISLE OF WIGHT DIVISION.**—A combined meeting of all Island practitioners to consider the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance will be held at the Mutz Hall, Newport, Isle of Wight, on Wednesday, January 21st, at 3.15 p.m. The arrangements are in the hands of Dr. W. J. A. Erskine, and Dr. Roberts, Upwey, Ventnor, secretary of the Local Medical and Panel Committee.

**SOUTHERN BRANCH: PORTSMOUTH DIVISION.**—A meeting of practitioners in the area of the Portsmouth Division will be held at the Corner House, Commercial Road, Portsmouth, on Thursday, January 22nd, at 5.30 p.m. Dr. G. C. Anderson, Deputy Medical Secretary, will open a discussion on the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance.

**SOUTHERN BRANCH: WINCHESTER DIVISION.**—A special meeting under the joint auspices of the Winchester Division and the Hampshire Local Medical and Panel Committees, and open to all members of the profession, will be held on Sunday, January 25th, in the Oldfellows' Hall, St. George's Street, Winchester, for the purpose of considering the draft Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance. The chair will be taken by Dr. Williams-Freeman at 2.30 p.m. Arrangements have been made whereby any practitioner living in the southern part of the county may attend either of the two following similar meetings if he finds it more convenient to do so: (a) Portsmouth—the Corner House, Commercial Road, on Thursday, January 22nd, at 3.30 p.m.; (b) Southampton—South Ham's Hospital, on Friday, January 23rd, at 8.45 p.m.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—A joint meeting of the Swansea Division and of the Panel Committee for Swansea has been arranged for Thursday, January 22nd, at 8 p.m., to discuss the evidence to be given before the Royal Commission on National Health Insurance. All members of the profession are invited, and copies of the SUPPLEMENT of January 3rd will be provided for non-members of the Association.—The Division will hold a medical clinic at the General Hospital on Thursday, January 29th, at 8.15 p.m.

**SOUTH-WESTERN BRANCH: EXETER DIVISION.**—The following course of lectures arranged for the spring of 1925 will be held in the library of the Royal Devon and Exeter Hospital, at 3.30 p.m., on the dates indicated: February 6th, Mr. Norman Lock: Intestinal Obstruction; March 6th, Dr. William Gordon: The Significance of Recent Work in Cardiology; April 3rd, Mr. R. Wayland Smith: Head Injuries; May 1st, Dr. F. A. Roper: Some Principles in Endocrinology. The lectures will be free to all members of the Association.

**SURREY BRANCH: CROYDON DIVISION.**—At the meeting of the Croydon Division to be held at the Croydon General Hospital on Tuesday, January 27th, at 8.30 p.m., Dr. Gordon Holmes, C.M.G., will read a paper on the distinction between functional and organic nervous diseases.

**SURREY BRANCH: GUILDFORD DIVISION.**—A meeting of practitioners in the area of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, at 3 p.m. on Thursday, January 22nd (instead of on January 15th, as previously announced) to consider the Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. The memorandum, as published in the SUPPLEMENT of the BRITISH MEDICAL JOURNAL of January 3rd, should be brought to the meeting. Dr. Cecil Lankester, chairman of the Division, will preside, and tea will be served at 4.30 p.m.—A meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, February 5th, at 4 p.m., when Dr. Charles Roberts will read a paper on radiology in general practice. Tea at 3.45 p.m.

**SURREY BRANCH: KINGSTON-ON-THAMES DIVISION.**—A meeting of the medical profession in the area of the Kingston-on-Thames Division will be held at the Surbiton Assembly Rooms, Surbiton, on Tuesday, January 20th, at 3.15 p.m. Dr. G. C. Anderson will open the discussion on the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance. Dr. H. R. Cran, vice-chairman of the Surrey Panel Committee, will preside.

**SURREY BRANCH: REIGATE DIVISION.**—An important Divisional meeting will be held, under the chairmanship of Dr. W. McD. Ellis, at the East Surrey Hospital, Reigate, on Sunday, January 18th, at 3 p.m., to which all medical practitioners, specialists, and consultants are invited, to consider the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance, and to pass the necessary resolutions. Dr. Percy Fry, a member of the Insurance Acts Committee and the Surrey Panel Committee, will address the meeting.

**YORKSHIRE BRANCH: HARROGATE DIVISION.**—A meeting of the Harrogate Division will be held in the Imperial Café on Thursday, January 22nd, at 8.30 p.m., when Mr. S. W. Daw, F.R.C.S. (Leeds), will give an address on orthopaedics and the nervous system.

**YORKSHIRE BRANCH: SHEFFIELD DIVISION.**—A meeting of the local medical profession, called jointly by the Sheffield Division of the British Medical Association and the Sheffield Local Medical and Panel Committees, will be held at the Church House, St. James Street, Sheffield, to-day (Friday, January 16th), at 8.30 p.m. Agenda: Consideration of draft Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance. Dr. Alfred Cox, Medical Secretary, has accepted an invitation to be present and will address the meeting. Discussion and questions will be invited.

**YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.**—The Wakefield, Pontefract, and Castleford Division is holding a special meeting for the consideration of the draft evidence for the Royal Commission on National Health Insurance at the Clayton Hospital, Wakefield, on Thursday, January 22nd, at 3 p.m., when the chair will be taken by Dr. William Steven (Featherstone), the Divisional chairman.

## Meetings of Branches and Divisions.

### BIRMINGHAM BRANCH: WEST BROMWICH DIVISION.

The annual meeting of the West Bromwich Division was held at the offices of the Smethwick Insurance Committee on January 6th. The retiring Chairman, Dr. BRADSHAW, gave an outline of the work of the Division during the past year. The membership was increased from 32 at December 31st, 1923, to 47 at December 31st, 1924. Four very successful meetings had been held during the year. In January Dr. E. H. K. Harries, of the Birmingham Fever Hospitals, gave a demonstration of the Schick test for diphtheria; in April Mr. H. W. Dawes (West Bromwich) read a paper on foot-and-mouth disease; in June Dr. H. G. Dain (Birmingham) opened a discussion on contract practice; in October Colonel L. W. Harrison of the Ministry of Health showed a film on the diagnosis and treatment of gonorrhoea in the male. Several very important matters were dealt with during the year. After prolonged negotiations contract practice rates were, he said, put on a better footing in West Bromwich and Wednesbury. The appointment of medical officer of health at a salary of £800 per annum West Bromwich Town Council assistant medical officer of health or annum, but a deputation from of the Town Council and the result was completely successful. The Smethwick Town Council tried to appoint a woman assistant medical officer of health and school medical officer at £500 per annum instead of at £600 per annum, the Association's minimum; their efforts were frustrated, and the appointment had now been filled at the adequate salary.

The following officers were appointed for 1925:

Chairman, Dr. R. W. Stocks (West Bromwich); Secretary, Dr. Dingley (Wednesbury). Representative in Representative Body.

The meeting discussed the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. It was arranged that separate meetings should be held in West Bromwich and Smethwick, that each meeting should answer the questions submitted, that each meeting should appoint a committee of five, and that those appointed should meet in West Bromwich on Sunday, January 25th, to decide finally the answers to be sent to the Medical Secretary of the Association.

The Chairman, Dr. R. W. Stocks, gave an inaugural address on the reduction of maternal and neo-natal mortality.

### ESSEX BRANCH: NORTH-EAST ESSEX DIVISION.

A meeting, to which all medical men resident in the area of the Division were invited, was held at the Red Lion Hotel, Colchester, on January 9th, to consider the draft Memorandum of Evidence proposed to be submitted to the Royal Commission on National Health Insurance. After sympathetic reference to the death of Dr. Caudwell of Coggeshall by the Chairman, discussion on the draft Memorandum was introduced by Dr. Cox, the Medical Secretary, who spoke in full detail on the various points contained in the Memorandum. The following, among others, took part in the subsequent discussion: Drs. FOX, HALL, ROWLAND, FELL, CLOWES, and COOX. A vote was taken on the items contained in the questionnaire in Document D.12, but owing to the limited time available the voting was somewhat cursory. The meeting concluded with a vote of thanks to Dr. Cox, proposed by Dr. CURLE.

### YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.

The third of the seven monthly lecture meetings arranged by the Wakefield, Pontefract, and Castleford Division for the present winter session was held at Wakefield on December 18th, 1924, when the Chairman, Dr. WILLIAM STEVEN, presided, and nearly sixty members and medical visitors were present.

The speaker of the evening, Sir BERKELEY MOYNIHAN, Bt., took as his subject the acute abdomen, and in a masterly address emphasized the salient diagnostic features of the various acute abdominal conditions in which early operation is imperative. Drs. OLDFIELD, THOMAS, CALLENDER, GREAVES, FLEMING, and others took part in the subsequent discussion.

## National Insurance.

### THE EVIDENCE TO THE ROYAL COMMISSION.

#### MEETING OF LONDON PRACTITIONERS.

A mass meeting of London practitioners to consider the draft Memorandum of Evidence proposed to be placed before the Royal Commission by the British Medical Association (SUPPLEMENT, January 3rd) was held at the Hotel Cecil on Sunday afternoon, January 11th. The attendance was greatly diminished as the result of a fog, which made travelling from certain of the suburbs almost impossible, but well over one hundred practitioners were present. The chair was taken by Dr. H. J. CARNALE, Chairman of the London Local Medical and Panel Committees, who was supported by Dr. H. B. Brackenbury, Dr. G. C. Anderson (Deputy Medical Secretary of the British Medical Association), and Drs. W. E. A. Worley and C. L. Batterson, secretaries respectively of the Metropolitan Branch Council and of the Local Medical and Panel Committees, whose names were jointly attached to the notice summoning the meeting.

Dr. BRACKENBURY said that the document must be considered as a whole; one section of it must not be entirely detached from the other sections. Even the question of dependants was intimately associated with the other proposals. This was not a memorandum which was to give any finality to the policy of the profession in this connexion. It was only when the report of the Royal Commission was issued, or, better still, when the proposals of the Government based on that report were made known, that the profession would be able to say that this or that proposal did or did not commend itself. He remarked upon the fundamental principles laid down in paragraph 8 of the document; in so far as any of those five principles were transgressed in any national health insurance scheme that scheme could not expect to gain the approval of the profession. It was true, of course, that such principles had to be reasonably and impartially applied, but they were the principles which must be held to govern the situation.

#### Inclusion of Dependants.

It was decided to take one by one the questions as already set out for meetings of the local profession (SUPPLEMENT, January 3rd, p. 9), the first being that of dependants, and Dr. BRACKENBURY gave a brief statement of the suggestions under that head. After describing what classes of persons it was suggested might be excluded from the scheme and what new classes of persons included, he said it was quite certain that in some way or other the State would make provision for the classes of poor persons whom the Memorandum proposed should be brought into insurance. The alternative would be a further increase of municipal and county treatment centres with whole-time salaried doctors. The far better way would be the provision of a family doctor for all these people. In reply to a question, Dr. Brackenbury added that if all the dependants of the present insured persons were brought in it was estimated that the insured population would number 38 million; this was altogether too gigantic a proposition. The suggestions in the Memorandum would involve an increase of the insured population probably to 28 million or 30 million, or practically double the present number. If the profession was to assume responsibility for this increased number certain other conditions must be met, such as the provision of a proper supply of nurses, the reduction of record-keeping to a minimum, and an entire revision of the present procedure with regard to complaints.

Dr. B. P. DOUZYOV said that at the beginning of national insurance the British Medical Association persuaded the profession to attend a very large section of the population for a very small sum. Now they were told that that section was to be largely increased. He called attention to the phrase "at any rate for the present," in paragraph 17. He believed that although the proposals at present might be partial, this was part of a movement to include the whole of the dependants, and to lead up to a national medical service. Up to now the scheme had included mainly manual workers—a relatively healthy population—but now it was proposed to take in those who were not manual workers and who were in many cases not fit for manual work. If a State Medical Service was brought in he was convinced that many practitioners would have nothing to do with such a scheme and would, if necessary, leave the country and work elsewhere.

Dr. F. G. LLOYD said that if the State was satisfied with the service rendered to the present insured persons and was willing to pay properly for dependants he saw no reason against their inclusion.

# Insurance: Evidence to the Royal Commission.

SUPPLEMENT TO THE  
BRITISH MEDICAL JOURNAL

Dr. S. F. HOLLOWAY thought that doctors serving under the Insurance Act had so far been fairly well satisfied. Certainly they were in a much better economic position than before the Act. He instanced a practitioner with a list of over 2,000; as it was, the dependants of these persons largely came under that practitioner's care, and for them he received an income of £400 a year. Was it likely that the State would offer no more than that?

Dr. J. MACKEITH argued against Dr. Brackenbury's view that municipal treatment centres were a menace to the general practitioner. These treatment centres, in the speaker's opinion, were most desirable things, and had accomplished something for the health of the community which would never be accomplished by the inclusion in an insurance scheme of dependants of insured persons. He believed that the panel system had been a disastrous failure, and he hoped there would be no extension to dependants or to other classes. For the benefit of the community it would be desirable to repeal the medical provisions of the Act.

Dr. PALMER opposed the inclusion of the dependants of all insured persons (which was the first proposition before the meeting) on the ground that many of the better-paid insured persons should be responsible for payment for medical attendance on their dependants, and also on the ground that, at all events in his area of South London, the practitioners could not cope with the work if this wholesale inclusion of the name must be made. Dr. R. CARSWELL said that it seemed to him obvious that any national health insurance scheme worthy of the name must include dependants. He was one of those who disapproved of the present insurance system, but he did not disapprove of insurance against sickness. Insurance should be radically altered from the provision of medical attendance. Dr. O'NEILL favoured the inclusion of the dependants of vision of the cost of medical attendance.

Dr. O'NEILL favoured the inclusion of the dependants of lower paid persons. If such persons were not included they would be taken in by the clinics.

The proposition favouring the inclusion in an insurance scheme of all dependants of all insured persons was then put, and lost by a large majority; only three or four hands were held up in its favour. The discussion continued on the question of including the dependants of only the lower-paid persons brought into the scheme as described in paragraph 16 of the document.

Mr. E. B. TURNER asked whether it was likely that any Royal Commission would report in favour of this proposal to the exclusion of the proposal to include all dependants. Would any Royal Commission recommend, or any Government propose to Parliament, the establishment of an income limit in the case of manual workers? Then there was the question of doctor-power. The insured woman worker had been very reasonable in her demands for medical attendance, but the case of women and their families would mean much heavier demands upon the doctor, and quite rightly, for children needed a great deal of care and treatment. During his forty-five years of a sheltered practice he had paid twenty-five visits to sick women and children to one visit he had paid to sick men. In industrial districts the result of what was now foreshadowed would be similar to the chaos in the middle of the war, when too many doctors were taken from civil practice. In these densely populated industrial districts every vestige of private practice would be swept away, and the objectionable division of the profession into panel and non-panel would be deepened and accentuated. The money spent on administration—already £7,000,000—would be vastly increased, and the bureaucracy that went with it. And did the profession think that if all dependants were taken on practitioners would be paid for all these new inclusions the same capitation fee as now? Finally, he complained that non-panel views had not been sufficiently represented in the preparation of the Memorandum. At the same time, although not himself an insurance practitioner, he was thoroughly in accord with nine-tenths of the document.

Dr. BRACKENBURY declared that the Memorandum had been prepared in the most impartial way, without any predominance of insurance practitioner interests. They were all agreed that in this matter the non-insurance practitioner was as vitally concerned as the man who was working the Act. Mr. Turner had been addressing himself to the proposition already negatived. All his arguments were against the inclusion of the number of dependants. But with regard to these people, it was not the profession did not make some suggestions that dependants of lower-paid persons it must be remembered that if the profession extended the system of treatment doctors would not fold its hands with regard to these people. It was one thing to think that this was economically element on the vision of a family doctor for all these poor persons, should the Commission think that the non-insurance element of the document consisted largely of consultants. The working non-panel

practitioner was practically not represented. Dr. BRACKENBURY said that one of the committees from which a report was received was the Non-Panel Committee, which did represent non-panel general practitioners.

A division then took place on the question: Is the meeting in favour of the inclusion in an insurance scheme of the dependants of only the lower-paid persons included in the scheme described in paragraph 16? A show of hands resulted in a tie, and the Chairman (Dr. Cardale) gave his casting vote in favour of the proposition. A demand, however, was made for a recount on the ground that the counting had been inaccurate, and a standing vote was taken. It was then found that the meeting was not in favour of the proposition, the numbers being: In favour 51, against 51.

**Poor Persons not under Contract of Service.**  
The meeting was then asked to say whether it favoured the inclusion of poor persons not under contract of service (para graph 18). Mr. TURNER and Dr. MACKEITH thought there would be considerable objection if it was proposed to compel such persons as small tradesmen of such persons could be collected. Dr. BRACKENBURY said that that was a difficulty, but all that was stated in the Memorandum was that if these administrative difficulties could be overcome there was no objection on the part of the profession to these people becoming insured persons. By a show of hands the meeting decided that it was not in favour of this inclusion.

**Poor Law Patients.**  
On the proposal to include the class of person at present attended under the Poor Law, Dr. E. A. GREGG hoped the meeting would not allow itself to be stampeded into turning down every proposition. He had been absolutely convinced as a result of his experience as a Poor Law guardian that it was impossible in Poor Law administration ever to get the status of the doctor raised substantially. The mentality of the average Poor Law guardian was such that the doctor under this system could hardly have the position which the profession would desire for him, and he thought that advantage should be taken of an opportunity like this to emancipate this section of the profession. Dr. A. E. CORRE hoped the position of existing officers would not be prejudiced in any transfer of this kind, and he pointed out how restricted was the amount of compensation which by statute a Poor Law officer might receive on removal from his post. Dr. BRACKENBURY said that there would be no difficulty in making specific provision in the paragraph to meet this point of view, and safeguard the present Poor Law medical officer.

The proposal was agreed to by 49 votes to 29.  
**Specialist and Consultant Services: Maternity Benefit.**  
The meeting was asked whether it agreed that the present service should at a convenient time be extended by the inclusion of specialist and consultant services. The reading of the question was greeted with loud cries of "Agreed."  
Mr. SYDNEY TIBBLES, in reply to a question, said that a very large number of ophthalmic surgeons had agreed already to help the rest of the profession to provide ophthalmic benefit in this scheme. The remuneration would be partly from the contributions of the insured persons and partly from those of approved societies.

The proposition was carried without dissent. Dr. BRACKENBURY gave a brief exposition of the proposals with regard to maternity benefit. The proposal to include within the scope of the scheme attendance at confinements and during the puerperal period, together with special examination and supervision during pregnancy, was negatived; there voted: In favour 27, against 55.

**Administration.**  
The meeting was next asked whether it approved the somewhat altered procedure in the case of official complaints suggested in paragraph 40. Dr. MACKEITH dissented from the proposal, who was under complaints against an insurance practitioner, who was under contract, must go through the normal channel of the lay authority. Dr. PALMER protested—in opposition to those actually engaged in this work could have any knowledge of the efficacy or otherwise of the present system. Dr. GEORGE JONES thought that if the medical profession joined itself together for the mixed tribunal to which it was at present subject under the Insurance Act. There would have to be an appeal, of course, either to the General Medical Council or to a common law court.

The meeting signified, without dissent, its approval of the suggestions of paragraph 40.

Approval was similarly given to the proposition that it was essential that "additional treatment benefits" should be grouped with medical benefit and removed from the control of the approved societies.

On the suggestions contained in paragraphs 43 to 46 as regards the future administration of an extended national health insurance service, after Dr. BRACKENBURY had described the position in some little detail, the meeting gave a vote in favour, with one dissentient.

The alterations in the rules of certification proposed in paragraph 51 were similarly agreed to.

#### Remuneration.

The CHAIRMAN then invited resolutions on other sections of the Memorandum.

Dr. MACKEITH complained of the arrangement suggested in paragraph 54, whereby the central body most properly representing the profession in negotiation on questions of remuneration was stated to be the Council of the British Medical Association.

Mr. E. B. TURNER, as a non-panel member of the British Medical Association, and one who had held the office of Chairman of Representative Meetings, assured Dr. MacKeith that he was quite wrong in supposing that the Association did not voice non-panel interests. A large number of non-panel doctors were members of the Association, and they had it in their power, if they wished, to bring their views before the Council and the Representative Body just as directly as any other section. Of course, national insurance had been the most "live" question in medical politics during the last few years, and the activities of the Association had been largely concerned in that direction. But although he himself was an uncompromising opponent of the Insurance Act, he felt that the Association was right in doing what it had done in the interests of the insurance practitioner, if for no other reason than that the remuneration and conditions of numerous other members of the profession engaged in all kinds of public service fluctuated with the insurance capitation fee. The Association, even when it was working on behalf of insurance practitioners, was really working on behalf of the whole profession. (Applause.)

Mr. T. P. BEDDOES said that in Germany, from which the national insurance system was derived, what corresponded to the British Medical Association in relation to the Insurance Act was a body devoted entirely to the safeguarding of the economic and financial interests of the profession. The British Medical Association prided itself on being a scientific institution, and that was, in his view, its weakness.

No resolution was moved, and the subject dropped.

On the motion of Mr. W. M. GABRIEL, it was agreed to recommend substitution of the phrase "dental surgeon or dentist" for "dentist" in paragraph 23, Mr. Gabriel pointing out that since the passing of the recent Act the term "dentist" had a technical significance and related strictly only to men registered under that Act.

A vote of thanks was accorded to the Chairman for his able conduct of the proceedings, and a similar compliment was paid to Dr. Brackenbury.

### MEMORANDUM OF EVIDENCE TO THE ROYAL COMMISSION.

#### MEETINGS TO BE HELD.

The following meetings have been arranged to consider the draft Memorandum of Evidence to be submitted by the British Medical Association to the Royal Commission on National Health Insurance. Further particulars of many of the meetings will be found in the announcements of forthcoming meetings of Branches and Divisions of the Association (SUPPLEMENT, pp. 37-39).

A meeting of all the Divisions of the British Medical Association and of the Panel Committee on Sunday, January 18th, at 3 p.m., in the Portman Rooms, 59, Baker Street, for the purpose of considering the draft Memorandum of Evidence, Dr. H. R. BRACKENBURY will explain the Memorandum, and discussion will follow. The Portman Rooms are three minutes' walk from Baker Street Station.

#### City Division.

At West Public Library, Thornhill Square, Islington, on Tuesday, January 20th, at 9.30 p.m.

At St. Leonard's, Shoreditch, Church Room (opposite Railway Station), on Wednesday, January 22nd, at 9.30 p.m.

#### Kensington Division.

At Kensington Town Hall, on Friday, January 23rd, at 3.30 p.m.

#### Kingston-on-Thames Division.

At the Surbiton Assembly Rooms, Surbiton, on Tuesday, January 20th, at 3.15 p.m.

#### Willesden Division.

At Willesden General Hospital, Harlesden Road, N.W., on Wednesday, January 21st, at 9 p.m.

#### Finchley Division.

At Finchley Memorial Hospital on Tuesday, January 20th, at 8.45 p.m.

#### Hamstead Division.

At Hampstead Town Hall, Haverstock Hill, N.W.3, on Thursday, January 22nd, at 8.30 p.m.

#### Woolwich Division.

At the Shakespearo Hotel, Powis Street, Woolwich, on Tuesday, January 20th, at 8.30 p.m.

#### Dartford Division.

At the Livingstone Hospital, Dartford, on Tuesday, January 27th, at 3 p.m.

#### Bromley Division.

At the United Services Club, London Road, Bromley, Kent, on Friday, January 16th, at 8.30 p.m.

#### Reigate Division.

At the East Surrey Hospital, Reigate, on Sunday, January 18th, at 3 p.m.

#### Guildford Division.

At the Royal Surrey County Hospital, on Thursday, January 22nd, at 3 p.m.

#### Portsmouth Division.

At the Corner House, Commercial Road, Portsmouth, on Thursday, January 22nd, at 3.30 p.m.

#### Isle of Wight Division.

At the Mutz Hall, Newport, Isle of Wight, on Wednesday, January 21st, at 3.15 p.m.

#### Winchester Division.

At the Oddfellows' Hall, St. George's Street, Winchester, on Sunday, January 25th, at 2.30 p.m.

#### Buckinghamshire Division.

In conjunction with the Bucks panel practitioners at the Crown Hotel, Aylesbury, on Friday, January 16th, at 3 p.m.

#### Derby Division.

In the Board Room of the Derbyshire Royal Infirmary, on Friday, January 23rd, at 3 p.m.

#### Lincoln Division.

At the offices of the Lincoln Insurance Committee, Palfrey Chambers, Silver Street, Lincoln, on Saturday, January 17th, at 8 p.m.

#### Holland Division.

At the White Hart Hotel, Spalding, on Friday, January 16th, at 3 p.m.

#### Norwich Division.

In the Medical Library, Norwich, on Wednesday, January 21st, at 8.30 p.m.

#### Leicester and Rutland Division.

At the Oriental Café, Market Place, Leicester, on Thursday, January 22nd, at 3.30 p.m.

#### Bedfordshire Division.

Joint meeting with the Panel Committee at Emerson Norman's Restaurant, 9, High Street, Bedford, on Wednesday, January 21st, at 3.15 p.m.

#### Oxford Division.

At the Radcliffe Infirmary, Oxford, on Wednesday, January 21st, at 3 p.m.

#### West Hertfordshire Division.

At the Abbey Institute, Romeland, St. Albans, on Sunday, January 18th, at 2.30 p.m.

#### South-West Essex Division.

At the Wesleyan Church School Rooms (near Leyton Station, Midland Railway), on Tuesday, January 20th, at 3.30 p.m.

#### Mid-Essex Division.

At Littleton Hall, Brentwood, on Sunday, January 18th, at 3.15 p.m.

#### Liverpool Division.

At the Medical Institution, 114, Mount Pleasant, Liverpool, on Wednesday, January 21st, at 3 p.m.

#### Sheffield Division.

In conjunction with the Sheffield Local Medical and Panel Committees, at the Church House, St. James Street, Sheffield, on Friday, January 16th, at 8.30 p.m.

#### Wakefield, Pontefract, and Castleford Division.

At Clayton Hospital, Wakefield, on Thursday, January 22nd, at 3 p.m.

#### Bury Division.

At the Derby Hotel, Bury, on Wednesday, January 21st, at 8.30 p.m.

#### Newcastle-upon-Tyne Division.

At the Medical Institute, 7, Windsor Terrace, Newcastle-upon-Tyne, on Tuesday, January 20th, at 8.30 p.m.

#### Cleveland Division.

At Worsley House, North Ormesby Hospital, Middlesbrough, on Tuesday, January 20th, at 3 p.m.

#### Sunderland Division.

Joint meeting with the Sunderland Panel and Local Medical Committees at 48, John Street, Sunderland, to-day (Friday, January 16th), at 8.30 p.m.

*Stockton Division.*

At Stockton and Thornaby Hospital on Wednesday, January 21st, at 4 p.m., and Friday, January 23rd, at 8.30 p.m.

*Swansea Division.*

At Swansea on Thursday, January 22nd, at 8 p.m.

*Dumfries and Galloway Division.*

At Royal Infirmary, Dumfries, on Thursday, January 22nd, at 3.30 p.m.

*Fife Branch.*

At the Station Hotel, Kirkcaldy, on Thursday, January 22nd, at 3 p.m.

As pointed out in the leading article published in the *JOURNAL* of January 3rd (p. 30), it is of great importance that every medical practitioner, whether serving under the Insurance Act or not, and whether a member of the British Medical Association or not, should attend the meeting in his district. The draft Memorandum of Evidence to be submitted to the Royal Commission was published in the *SUPPLEMENT* of January 3rd, and it is hoped that members attending will take it to the meetings.

## THE ROYAL COMMISSION.

The twelfth meeting of the Royal Commission on National Health Insurance was held at the Home Office on January 8th, Lord Lawrence of Kingsgate in the chair. The examination of Mr. Edwin Heather, representing the Independent Order of Oddfellows, Manchester Unity, was continued on the following subjects: dental benefit, extension of medical benefit, the benefits of married women deposit contributors, exempt persons.

Proof copies of the oral evidence given at the meetings of December 11th, 18th, and 19th, 1924, may be obtained, on remittance of cost and postage, from H.M. Stationery Office, Adastral House, Kingsway, W.C.2. Evidence of December 11th and statement submitted by National Conference of Industrial Assurance Approved Societies, price 1s. 6d.; evidence of December 18th, price 1s. 6d.; evidence of December 19th and statement submitted by the Independent Order of Oddfellows, Manchester Unity, price 1s. 6d.

## Correspondence.

## ROYAL COMMISSION ON NATIONAL INSURANCE.

SIR,—Mr. Turner has spent a lot of ink in dealing with a situation with which the profession is not faced, and with which it may never be faced. If ever it has to choose between the inclusion of all the dependants of insured persons as at present defined in a national health insurance scheme or the inclusion of none of them, the choice would no doubt be made with full consideration of all the facts so well put by Mr. Turner. The opinion expressed in the draft Memorandum of Evidence is that the inclusion of all these dependants would not be wise, and would not be acceptable to the British Medical Association. With this opinion it appears that Mr. Turner is in agreement. So are his colleagues on the Council. It is a pity that he should suggest disagreement where none exists.

The present position is, however, that the Association proposes to suggest to the Commission that there is a better way—namely, to draw a line below which, in general, assistance is required to secure medical advice and treatment for dependants, and to provide it for these, and for these only, by an insurance plan. The Royal Commission, or Parliament, may find that there are serious difficulties in doing this; but it would be foolish to assume that these are insuperable, and therefore to refrain from supporting a suggestion which, if it can be carried out, is obviously more advantageous to the national health and less disadvantageous to the profession than any alternative method which has been suggested.

For there can be no doubt that the State will in some way make provision for attending to the health of these poor people. At present it is doing this very imperfectly and with many restrictions by means of municipal and county treatment centres of various kinds. Even under the present limitations these are becoming more numerous and more firmly established, and they are undermining the position of the private practitioner and gradually destroying his practice as a family doctor. It will, in my view, be impossible permanently to maintain the restrictions as to kind of illness treated or the prohibition of domiciliary attendance which at present attach to this method of

provision. Family private practice will then be finally destroyed with regard to a large proportion of the population. It is to be hoped that the meetings of the profession now being held will support the Council in its belief that it is imperative to seize this opportunity of suggesting that a far better and more effective method is through an insurance scheme, to provide a doctor of his own for each of these poor persons, so that they may be placed in the same position and advised in a similar way as those who are economically better off.

Strong objection must be taken to Mr. Turner's statement that "this draft of evidence has been prepared and submitted practically by the Insurance Acts Committee." This is not in accordance with the fact. It was submitted to and approved by, the Council, by a large meeting of joint committees after full consideration of reports from four special subcommittees presided over by Sir Thomas Horder, Sir Ewen Maclean, Professor H. R. Dean, and Dr. Badoock, and of reports also from the Non-Panel Committee of the Council and from a special Committee on Ophthalmic Benefit. Substantial portions of the Memorandum are in the exact words of these reports, and it embodies also the findings of the Hospitals Committee so far as they are relevant to the matters discussed. There can be no question as to the full and impartial preparation and consideration of the draft.—I am, etc.,

London, N.4, Jan. 10th.

HENRY B. BRACKENBURY.

SIR,—Mr. E. B. Turner (*SUPPLEMENT*, January 10th, p. 25) has voiced in concentrated form the undoubted opinions of general practitioners who are not insurance practitioners, many of whom are beginning to look with alarm on what appears to be a proposal to make a second and further raid into their private practices by roping in another 50 per cent. for an insurance scheme.

Some of the most important arguments against his position, however, are not those which can be very well stated in the public medical press, and therefore it is the more incumbent on every area, in making its arrangements to discuss the suggested Memorandum of Evidence giving the views of our profession, to be sure to have at its meeting one or more who have been behind the scenes in its preparation. As the travelling expenses are being paid by the Association there can be no excuse for hesitancy.

But what one is more concerned with is the warning in your leading article (*BRITISH MEDICAL JOURNAL*, January 3rd, p. 30, col. 2), where you very correctly state—

"It is clearly to be understood that the Memorandum of Evidence to be submitted to the Royal Commission will contain merely suggestions—though suggestions of wide-reaching importance—which the profession thinks it well to place before, or even to urge upon, the Royal Commission."

And again—

"But it should at the same time be remembered that it will be almost impossible later to oppose proposals substantially in the same form as suggestions made by the profession itself in its evidence."

The whole of the activities of the British Medical Association for the past twenty-one years have been concentrated in an endeavour to secure the confidence of members of our profession in itself as having provided the most up-to-date and efficient local machinery for securing full discussion by all sections in our profession of all questions affecting medical policy, with a subsequent opportunity for a central discussion and an endeavour there to come to some common line of action. This machinery has been provided by the Divisions and the Representative Body of the Association, the latter consisting as it does of representatives called together from all parts of the United Kingdom and beyond. To a great extent this endeavour has proved successful; and many who have not felt directly interested in medical politics have relied on this machinery and become willing loyally to abide by the decisions come to.

But what is the proposal before the profession now? It is that there should be a hybrid meeting of individual members of our profession to determine a policy for it. Not a meeting of the Representative Body, not a meeting of the Panel Conference; but an amalgam of the two. As Mr. Turner rightly says, the logical demand is that an equal number of non-insurance practitioners should be invited

to meet the Representative Body in order to balance the 200 or more practitioners forming the Conference of Panel Practitioners. That would give the final Gilbertian touch the original proposal requires.

It is idle to protest, as some do, that at some later date the profession must, and will be able to, consider its policy on the fundamental questions as they are elaborated now in this Memorandum of Evidence. It will have become too late. As you rightly say, "it will be almost impossible later to oppose proposals substantially in the same form as suggestions made by the profession itself in its evidence."

It is to be hoped, therefore, that all the Divisions of the Association will insist—by adoption of definite resolutions at their forthcoming meetings—in demanding that a special meeting of the Representative Body be called to consider this Memorandum of Evidence, together with the decisions of this conjoint conference and any further information the Council cares to place before it, before any document of evidence is forwarded to the Royal Commission. This can easily and inexpensively be arranged for the day succeeding the conference.

Only in this way can any continuation of unity be hoped for in our profession at this time of the further elaboration of a national health service.—I am, etc.,

Hove, Jan. 10th.

E. ROWLAND FOTHERGILL.

SIR,—In the draft Memorandum of Evidence (Document D. 11, para. 15) some doubt is expressed as to the ability of the doctors to undertake the additional work involved. Mr. E. B. Turner, in the SUPPLEMENT of January 10th, says it would be impossible to find the doctor-power to work the scheme, and similar doubts were expressed at the London meeting on January 11th.

But is the work going to be increased to such an extent? At present the dependants of the insured person do receive medical attention; usually they are private patients of the breadwinner's panel doctor. If dependants came under an insurance scheme the only difference would be that the doctor would be paid in a different manner for doing the work he is doing at present, and he would have no book-keeping and no bad debts.

The question before the profession is, "Shall these patients be looked after by an extension of the present clinic system or shall the family doctor be responsible for all the preventive medicine and treatment the family requires?" Recently I had the opportunity of obtaining the views of a number of doctors in connexion with the proposed formation of a local public medical service. I think doctors would welcome the inclusion of dependants, so that each family would have its doctor, but the remuneration must be adequate.

But none of us want an extension of the present clinic system, whereby our patients are sent by nurses (of whom we know little) to see so-called specialists (of whom we know less). If a doctor finds he has extra work and has to get help, he is not only serving the State by practising preventive medicine, but he is improving his own standing and helping to absorb into general practice some of the junior men at present without a post.

It is to be hoped that doctors will seize the opportunity, if it is given them, to be the doctors of the nation. If they do not, one can foresee that in ten years' time the general practitioner, after watching his practice dwindling under the inroads of various voluntary and municipal clinics, will only be permitted two functions. One will be, I think, to sit in his "office," as it will then rightly be called, and issue printed tickets telling his patients which clinic or "specialist" to consult. Of the second I am certain: he will be permitted to continue to pay income tax, rates, and taxes to help to keep all the schemes going.—I am, etc.,

London, W.10, Jan. 13th.

A. KEITH GIBSON.

#### Remuneration of Rural Practice.

SIR.—Truly the rural doctor's income is being very thoroughly pared. Notwithstanding the feeling remarks on our position that are made at various conferences, I am given £126 as a mileage allowance for a panel spread over a wide and sparsely populated district, which necessitates my running 5,600

miles a year at least on insurance work. This works out at sixpence a mile almost exactly.

Our capitation fee is the same as that of town doctors, so that I cannot understand how the sum given for mileage can be considered adequate for the running expenses of a stout car, quite apart from the time spent on the road and the time and work required to keep the car in a condition to travel on the road.

Why should a professional man working for a Government department not receive as much remuneration as a taxi-driver for the same work? Do our ears cost less to run? Can we buy ears more cheaply? Do we get any rebate of ear tax? Where then does the adverse balance come from? Out of our capitation grant, or otherwise out of our pockets. Verily is the country profiteering at our expense.

I have kept silence with great difficulty for some time past, but now have "boiled over," and hope that many other country doctors will add their tales of woe to mine.—I am, etc.,

Coldingham, Berwickshire, Jan. 8th.

F. O. TAYLOR.

#### Pensions for Panel Practitioners.

SIR,—May I appeal to all panel practitioners who attend the meetings held to discuss what evidence shall be submitted to the Royal Commission to voice a determined support to the slogan "No extensions without pensions"? A sad blunder was perpetrated in permitting the present Insurance Acts to come into operation without this logical corollary. Especially should the younger men, just entering the profession, remain firm on this question. We are now, for better or worse, Civil servants. Then we are entitled to the same treatment as all other Civil servants.—I am, etc.,

Hove, Jan. 13th.

A. A. HILL.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

SURGEON COMMANDERS H. BURNS, O.B.E., to the *Frigate*; A. B. Cox to H.M. Dockyard, Devonport; J. M. Gordon to the *Emperor of India*; W. Bradbury, D.S.O., to R.N. College, Greenwich; F. H. Holl to the *Royal Oak*, temporary.

SURGEON LIEUTENANT COMMANDERS W. H. Murray to the *Osprey*, additional; G. H. Hayes to the *Tiger* and F. G. Motton to the *Victory* for R.N. Barracks; R. A. J. MacKenzie to R.N. College, Dartmouth. SURGEON LIEUTENANTS J. J. O'Reilly to the *Clematis*; E. V. Barnes to the *Resolution*.

### ROYAL ARMY MEDICAL CORPS.

The following Majors to be Lieutenant-Colonels: Brevet Lieut.-Colonel H. V. Bagshawe, C.B.E., D.S.O., vice Lieut.-Colonel W. F. Ellis, O.B.E., to half-pay; R. J. Franklin, vice Lieut.-Colonel H. S. Anderson, C.M.G., to retired pay.

### ROYAL AIR FORCE MEDICAL SERVICE.

Wing Commander H. A. Treadgold to Central Medical Board, Hampstead, for duty as medical officer. Squadron Leader P. M. Keane to the R.A.F. Depot on transfer to Home Establishment. Flying Officers W. B. Stott to R.A.F. Depot on transfer to Home Establishment; R. S. MacLachy to Palestine General Hospital.

### VACANCIES.

BIRMINGHAM GENERAL HOSPITAL.—Medical Registrar and Resident Medical Officer. Salary £155 per annum.

CHELTENHAM GENERAL AND EYE HOSPITAL.—Honorary Pathologist.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, Victoria Park, E.2.—House-Physician (male). Salary at the rate of £125 per annum.

DERBYSHIRE EDUCATION COMMITTEE.—Assistant School Medical Officer (woman). Salary £600 per annum, rising to £700.

ELIZABETH GARRETT ANDERSON HOSPITAL, Euston Road, N.W.1.—(1) Assistant Pathologist (female); salary £150 per annum. (2) Assistant Anaesthetist.

EVELING HOSPITAL FOR CHILDREN, Southwark, S.E.—(1) Physician to Out-patients (honorary). (2) House-Physician (male); salary at the rate of £120 per annum.

EXETER ROYAL DEVON AND EXETER HOSPITAL.—Medical Officer in charge of Venereal Clinic. Salary £400 per annum.

FREMINGTON HOSPITAL AND NURSING HOME, 237, Fulham Road, S.W.3.—The whole of the Medical and Surgical Staff.

Irmond Street, W.C.1.—Casualty

Road, N.W.1.—Medical Registrar.

MANCHESTER CITY.—Two Assistant Medical Officers at the Baguley Sanatorium. Salary £350 per annum.

MANCHESTER: ST. MARK'S HOSPITAL.—House-Surgeon for the Whitworth Park Hospital (Gynaecological and Children). Salary at the rate of £50 per annum.

METROPOLITAN ASYLUM BOARD.—(1) Director of the Pathological Services. (2) Director of the Diphtheria Antitoxin Establishment. Salary £1,100 and £500 per annum respectively.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, Fitzroy Square, W.—House-Surgeon. Salary £100 per annum.

M.—Assistant Medical Officer (non-

— EAST LONDON, Greenwich Road, S.E.10. inas per annum.

— AND EPILEPTIC, Queen Square, W.C.1.

NORWICH: JENNY LIND HOSPITAL FOR CHILDREN.—Resident Medical Officer (male). Salary £150 per annum.

NOTTINGHAM GENERAL HOSPITAL.—House-Surgeon. Salary £150 per annum.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.—Venereal Diseases Department (female). (1) Medical Officer in charge of Department. (2) First Assistant. (3) Second Assistant. Females. Salary for (2) £550 per annum, and for (3) £5 5s. per week.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, W.C.2.—Assistant House-Surgeon for three months.  
 ST. MART'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.15.—Honorary Assistant Physician.  
 STAFFORDSHIRE EDUCATION COMMITTEE.—Assistant School Medical Inspector. Salary £600 per annum, rising to £800.  
 WAKEFIELD: £175 per an.  
 WEST LONDON: " al  
 Registrar: " al  
 WOOLWICH: " ng  
 Officer in l to 1700.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the following vacant appointments: Patterdale (Westmorland), Great Wakering (Essex).

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

### APPOINTMENTS.

BOWIE, E. Ormond, L.A.H., D.P.H.Dub., Medical Superintendent of Strickton House, Church Street, Shropshire.  
 DOUBLEDAY, F. M., L.R.C.P.Lond., M.R.C.S., L.D.S.Eng., External Examiner in Dental Subjects to the University of Bristol.  
 SAWAY, A. Ernest, M.B., B.S.Lond., M.R.C.S., L.R.C.P., Honorary Surgeon to the Derbyshire Hospital for Sick Children.  
 STURRIDGE, F. R., M.C., M.R.C.S.Eng., L.R.C.P.Lond., a member of the Honorary Medical Staff of the Wilkesden General Hospital.

### DIARY OF SOCIETIES AND LECTURES.

#### ROYAL SOCIETY OF MEDICINE.

Social Evening, Mon., 8.30 p.m. Reception by the President, Sir S. Clair Thomson. 9.20 p.m., Address by Miss Lena Ashwell on The Drama as a Necessity of Civilized Life. Sir Thomas Legge will give an exhibition of Fifteenth Century Stained Glass.  
 General Meeting of Fellows, Tues., 5.30 p.m.  
 Section of Pathology: Tues., 8.30 p.m., Dr. R. A. O'Brien and Miss B. I. Range. The Testing of Antidyphtheria (Stigma) Serum; Dr. J. A. Murray: Tar-enteronemia in Rabbit and Rat; Messrs. A. T. Gienny and C. G. Pope: Explanation of the Toxicity of Frozen Diptheria Toxin-antitoxin Mixtures; Drs. C. C. Okell and H. J. Parish: Results of Further Dick (Scarlet Fever) Tests.  
 Section of History of Medicine: Wed., 5 p.m., at the Wellcome Historical Medical Museum, 54a, Wigmore Street, W. Mr. C. J. S. Thompson: Anatomical Manikins; Mr. Alban Doran: Ancient Bed Bottles and Uroscopy. Mr. Thompson will exhibit drawings and specimens of uroscopic Glasses.  
 Section of Epidemiology and State Medicine: Thurs., 5.30 p.m., Dr. F. E. Wynne: Overcrowding and Epidemic Disease.  
 Section for the Study of Disease in Children: Fri., 8.30 p.m., Discussion: Pneumococcal Peritonitis; to be opened by the President, Dr. H. C. Cameron, followed by Mr. G. E. Waugh, Mr. John Fraser, and Dr. D. Nabarro.  
 ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.1.—Sir Arthur Keith, 5 p.m., Mon., Antiquity of Man in South Africa; Wed., The Rhodesian Skull; Fri., Java and their bearing on the The  
 HENRIETTA SOCIETY, Mansion House, Lectures  
 by Mr. G. Grey Turner: Perfora Ulcera, and After.  
 MANCHESTER CLINICAL SOCIETY.—Medical Society's Reading Room: Wed., 4.30 p.m., Lecture by Mr. James Sherrett: Acute Haematemesis and Melæna.  
 MEDICO-LEGAL SOCIETY, 11, Chandos Street, W.1.—Tues., 8.30 p.m., Mr. F. Llewellyn Jones: Laws of Nations and the Health of Nations.  
 UNIVERSITY COLLEGE, Gower Street, W.C.1.—Mon., 5 p.m., Professor G. Elliot Smith, F.R.S.: The Anatomy and Physiology of the Sympathetic Innervation of the Striated Muscle.

#### POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Lecture, Tues., 5.30 p.m., Treatment of Fractures. West End Hospital for Nervous Diseases, 75, Welbeck Street, W.1: Intensive Course in the Diagnosis and Treatment of Common Diseases of the Nervous System, Daily, at 5 p.m., Lectures, including Clinical Demonstrations on Cases, Bethlem Royal Hospital, St. George's Fields, S.E.1: Tues. and Sat., 11 a.m., Lecture Demonstrations.  
 HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Tonsils and Adenoids.  
 NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Daily: In-patient and Out-patient Clinics, special Departments. Lectures and Demonstrations. Fri.,

St. JOHN'S HOSPITAL, 49, Le Lectures:  
 Tues., 5 p.m., The Erythemas; Thurs., 5 p.m., Lupus Erythematosus.  
 ROYAL DENTAL HOSPITAL, Leicester Square, W.C.2.—Fri., 5 p.m., Fundamental Facts of Dead Teeth and of the Methods employed in Treatment.  
 ST. ANDREW'S INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., The Eye and the Kidney. Thurs., 4 p.m., Demonstration of Kidney Cases in the Dundee Royal Infirmary. (Tues., Jan. 27th, Clinical Application of Tests for Renal Efficiency. Tues., Feb. 3rd, Albuminuria in Children and Adults.)  
 WEST LONDON: Mon., 12 noon, Chest Cases. Wed., 12.15 p.m., X a.m., Gynaecological Ward. Fri., 12 noon, Children. Dr. Patients, Operations, Special Departments.  
 GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Western Infirmary: Wed., 4.15 p.m., Surgical Cases. At Royal Infirmary (Gynaecological): Mon., Shaw Street a.m., Mon. 10 a.m. Medical Diseases of a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.  
 At Western Infirmary: Wed., 4.15 p.m., Surgical Cases. At Royal Infirmary (Gynaecological): Mon., Shaw Street a.m., Mon. 10 a.m. Medical Diseases of a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.  
 At Western Infirmary: Wed., 4.15 p.m., Surgical Cases. At Royal Infirmary (Gynaecological): Mon., Shaw Street a.m., Mon. 10 a.m. Medical Diseases of a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.

## British Medical Association.

OFFICES AND LIBRARY, 122, STRAND, LONDON, W.C.2.

### Reference and Lending Library.

The Reading Room, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.  
 LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 6d. for each volume for postage and packing.

### Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS (Financial Secretary and Business Manager): Telegraphs: Articulate Westrand, London).  
 MEDICAL SECRETARY (Telegrams: Mediteora Westrand, London).  
 LONDON, British Medical Journal (Telegrams: Antiology Westrand, London).  
 Telephone number for all departments: Gerrard 2630 (3 lines).  
 SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: el; 4261 Central).  
 IRELAND MEDICAL SECRETARY: Frederick Street, Dublin. (Telegrams: 4737 Dublin).

### Diary of the Association.

(For meetings called to discuss the Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance see page 41.)

- JANUARY.
- 16 Fri. Mid-Cheshire Division: Altrincham General Hospital, B.M.A. Lecture by Dr. S. A. Kinzier Wilson on Neuritis and Neurasthenia, 8.45 p.m.  
 Northern Counties of Scotland Branch: Palace Hotel, Inverness. B.M.A. Lecture by Professor A. Mackintosh on Neurological Musings, 6.30 p.m. Dinner, 7.30 p.m.  
 20 Tues. London: Medical Officers of Schools Subcommittee, 2.30 p.m. Lewisham Division: Parish Room, St. Laurence Vicarage, Catford. Paper by Mr. A. Ryland on Danger Signals, 8.45 p.m.  
 Newcastle-on-Tyne Division: Armstrong College. Address by Dr. William Brown on Psychiathery, 5.30 p.m.  
 21 Wed. Bedfordshire Division: Emerson Norman's Restaurant, 9, High Street, Bedford, 3 p.m.  
 Chesterfield Division: Annual Dinner, Station Hotel. Address by Dr. Brackenbury, 7.30 p.m.  
 South Middlesex Division: St. John's Hospital, Tickenham. Discussion on Scarlet Fever from a Public Health Point of View; to be opened by Dr. H. A. Gunther, 8.15 p.m.  
 22 Thurs. Dumfries and Galloway Division: Royal Infirmary, Dumfries, 3.30 p.m.  
 Harrogate Division: Imperial Café. Address by Mr. S. W. Daw on Arthropodæ and the Nervous System, 8.30 p.m.  
 Nuncaton and Tamworth Division: Tamworth General Hospital. Paper by Dr. K. D. Wilkinson on Cardiac Irregularity.  
 23 Fri. Hyde Division: Supper Dansant, Oaklands, Mottrian New Road, Hyde, 8.30 p.m.  
 27 Tues. Croydon Division: Croydon General Hospital. Paper by Dr. Gordon Holmes on the Distinction between Functional and Organic Nervous Diseases, 8.30 p.m.  
 28 Wed. London: Organization Committee, 2 p.m.  
 Bath and Bristol Branch: Clinical Meeting, Bristol.  
 Oxford Division: Radcliffe Infirmary. Paper by Mr. Hayward Finch on Radium Therapy, 2.30 p.m.
- FEBRUARY.
- 5 Thurs. London: Joint Meeting of Royal Commission and Insurance Acts Committee.  
 Guildford Division: Royal Surrey County Hospital, Guildford. Paper by Dr. Charles Roberts on Radiology in General Practice, 4 p.m.  
 6 Fri. Exeter Division: Royal Devon and Exeter Hospital. Lecture by Mr. Norman Lock on Intestinal Obstruction, 5.30 p.m.  
 10 Tues. City Division: Metropolitan Hospital, Kingsland Road. Paper by Dr. Edwin Smith on Some Legal Relationships of the Practitioner, 9.30 p.m.  
 12 Thurs. Castleford Division: Bull Restaurant. Paper by Mr. S. W. Daw on Modern Supper, 8 p.m.  
 18 Wed. London: Special Meeting of Council, 10 a.m.

### BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

#### BIRTH.

FINDLAY.—At a nursing home in Glasgow, on November 20th, to Captain and Mrs. Findlay, I.M.S., a daughter—both well.

#### MARRIAGES.

BOYD-HOLTON.—On January 6th, at St. John's Church, Finsbury Park, by the Rev. Canon Buckley and the Rev. H. Casson, Thomas Fraser, eldest son of Mr. and Mrs. G. H. Boyd of St. Peter's, Thamel, to Patricia Nina, younger daughter of Dr. and Mrs. Holton of Maxton, Elstree, and granddaughter of the late Surgeon-General F. Holton, M.B., A.M.S.  
 THOMSON-RENNET.—At St. Clement's Episcopal Church, Aberdeen, on December 29th, Ian Stewart Thomson, M.A., M.D., D.P.H., Southampton Isolation Hospital, second son of Professor J. Arthur Thomson, Aberdeen University, to Sadie, younger daughter of Ernest Rennet, Advocate in Aberdeen.

WEBBER-REIDER.—On December 23rd, 1924, at the Church of St. Simon Stock, Putney, Harold Norrils Webber to Madeleine Mary Ryder.

#### DEATHS.

DINGLE.—Lilian Mary Dingle, L.R.C.P. and S. (née Grandin, The Magnolias, Jersey), on December 5th, 1924, of typhus, at Chao-Tong, Yunnan, China. (By cable.)  
 PREBBLE.—On January 10th (suddenly), at 6, St. Albans Place, Blackburn, Philip Prebble, M.B., C.M.Aber. 1835, aged 59 years.

#### CURRENT NOTES.

##### Secret Commissions.

Two recent instances in which secret commissions have been offered to medical men have been brought to the notice of the Medical Secretary. In the first case, a company selling rubber goods informed a medical man that tho thought had occurred to them that he might be inclined to recommend to his patients the goods sold by them, and that they were accordingly "writing confidentially to make the businesslike proposition to allow you a commission of 20 per cent. on all orders we execute through your recommendation." Another company—makers of surgical instruments—after fitting the patient of a medical man with a truss, had "pleasure in asking your acceptance of the enclosed remittance for 7s. 11d., being a special professional discount of 15 per cent. on the transaction." Apart from the legal risks persons making and accepting such offers run, it should be obvious to business people that the suggestion is one which is very objectionable to members of the medical profession. Members receiving such offers are requested to send the information to the Medical Secretary, and also to endeavour to make plain to the firm making the offer that, so far from advancing their interest, such an offer prevented any more business being done with that firm.

##### A Bogus Doctor.

A warning is issued against a bogus doctor, who has lately been victimizing members of the profession and their relatives, especially in the London area. The man, who is said to be fairly well educated and of smart appearance, calls upon doctors or Irish people and claims acquaintance with their relatives or friends living in Ireland. Saying that he has obtained an appointment in Ireland, or that for some other reason he has to go to Ireland that evening and has run short of cash, he asks where he can cash a cheque or for a money loan. He has at various times given the name of Fitzgerald, Moore, Rogers, Black, McCormack, O'Brien, or Murphy. He is about 40 to 45 years of age, 5 ft. 10 in. in height, with dark hair streaked with grey and brushed back, grey or blue eyes, clean shaven, and generally dressed in a grey lounge suit, light grey overcoat, and soft felt hat. It is suggested that anyone approached by this man should communicate at once with the Commissioner of Police, New Scotland Yard, Parliament Street, S.W.1 (Telephone: Victoria 7000).

### THE EVIDENCE TO THE ROYAL COMMISSION.

#### MEETING OF MIDDLESEX PRACTITIONERS.

A MEETING of the medical practitioners of the county of Middlesex was held under the auspices of the Divisions of the Association in that area and of the Panel Committee on Sunday afternoon, January 18th, in the Portman Rooms, Baker Street, for the purpose of considering the draft Memorandum of Evidence proposed to be presented to the Royal Commission on National Health Insurance (SUPPLEMENT, January 3rd, pp. 1-9). About eighty were present. Dr. H. DISTIN, Chairman of the North Middlesex Division, was voted to the chair.

#### Dr. Brackenbury's Statement.

Dr. H. B. BRACKENBURY said that the draft Memorandum had been laboriously and impartially prepared, and represented the result of a great deal of consideration of very difficult problems. It would be a pity if any meeting of medical men should turn down lightly propositions which had been the outcome of so much careful exploration. Propositions which at first sight did not recommend themselves to those who came to them freshly might prove to be the only feasible propositions after more lengthy consideration. In Middlesex, at all events, he was glad to think that the profession had got out of the atmosphere of twelve years ago, when there was a rivalry between insurance and non-insurance practitioners as to which could pull the more chestnuts out of the fire, and the profession was prepared now to approach these problems in a statesmanlike spirit. Dr. Brackenbury then repeated in substance the speech he delivered at the mass meeting of London insurance practitioners the previous Sunday (SUPPLEMENT, January 17th, p. 39). The five principles laid down in paragraph 8 of the Memorandum were essential, and their application must be reasonable and impartial. He drew attention to three difficult problems. The first was the proposed inclusion of certain new classes of people—dependants and others—in national insurance and the exclusion of certain existing classes. Insured persons at present included many who were just as well able to provide medical attendance for themselves as those who were not insured. It was suggested that such people as clerks in the large banks and insurance offices, who had security of employment and a superannuation scheme, should come into the category of persons excluded, as did Civil servants and certain other classes at the present time. Persons with certain small private incomes, who might at present at their own option take themselves out of insurance, should be excluded. Further, it was suggested that the income limit should be applied, not merely to the clerical worker, but to the manual worker also. But if people above a certain line were excluded, it would be illogical to argue against the inclusion of any below that line. A second question of some difficulty was the relation of the medical officer to these provisions for poor persons. He would give the medical officer of health a very important role, associating him with the elected chairman of the Local Medical Committee in settling disputes or investigating complaints which might arise in connexion

with this service. A third difficult point was the relationship of maternity work to the insurance scheme. The absolute freedom of every practitioner to say whether he would or would not take part in maternity practice must be preserved, but it was proposed that at all events for insured women the provision of a midwife should be included in the benefit which she received from insurance, and that as part of this scheme, as well as of the general scheme, the advice and help of consultants and sufficient institutional provision must be forthcoming to make maternity benefit an effective part of national insurance.

#### Discussion.

The discussion which ensued upon this introductory speech was informal, and was mainly in the nature of questions directed to Dr. Brackenbury with a view to further enlightenment on specific points. The questions chiefly related to the conditions likely to arise from the inclusion of dependants. Dr. Brackenbury said that if practitioners were to assume this additional work and responsibility it was essential that better nursing help should be available, statistical records must be reduced to the minimum, and there must be an alteration of the quasi-judicial machinery for dealing with complaints. With regard to remuneration, those who had drawn up the Memorandum saw no reason why the rate should be lower in the case of the new entrants. Certification, of course, would not be necessary in the case of dependants, except possibly in the very minor matter of school certification.

A show of hands was called for on the question whether the meeting was in favour of the inclusion of all dependants of all insured persons. Not one hand was held up in the affirmative.

On the more debatable question of the inclusion of dependants of only the lower-paid persons, Dr. W. R. Wilson asked whether it would be to the advantage of the public to increase contract practice to the great extent foreshadowed. Contract practice, at all events up to the time of the Insurance Act, was not considered the best form of practice. Moreover, in this case it had the effect of creating a "corner," which made it very difficult for a young man newly entering practice to secure a livelihood. Dr. BRACKENBURY said that with absolute free choice of doctor at any time a young man putting his name on the panel had very much the same kind of opening under the Insurance Act as he had in private practice. Dr. WINSTON and Dr. S. F. HOLLOWAY spoke in favour of the inclusion of dependants of lower-paid persons, and on the question being put to the meeting it was answered in the affirmative, 44 voting in favour and 10 against. The meeting also unanimously assented to the view that if any dependants were included it was essential to secure the provisions for lessening work as set out in paragraph 15. Without discussion the meeting signified itself in favour of the inclusion of poor persons not under contract of service and of that class of person at present attended under the Poor Law.

With regard to specialist and consultant services, Dr. BRACKENBURY said that if the consultant came in it was very desirable that he should come in under conditions which were assimilated as far as possible to those of private practice—that is to say, he should not be obliged to do his work through clinics or institutions provided for the purpose.

The extension of the service by the inclusion of specialist and consultant services was approved unanimously, but some discussion took place on the order in time in which these developments—in the one case the inclusion of dependants, and in the other case the extension to consultant and specialist services—should come into force, supposing the two could not take place simultaneously. Dr. C. F. T. SCOTT was of opinion that the two schemes must go together, so that there was really no question of priority. Dr. S. C. EVANS spoke in favour of the inclusion of dependants as the first resort, and Dr. A. G. NEWELL in favour of the inclusion of consultants and specialists. Dr. BRACKENBURY said that he had no wish to influence the meeting one way or the other, but in fairness to consultants and specialists who were probably not present that afternoon, it had to be remembered that if the inclusion of dependants was taken first it would mean that for some time the services of consultants and specialists would continue to be exploited. On the matter being put to the vote, 40 voted in favour of extension in the first place to specialist and consultant services, and 25 in favour of the inclusion of dependants in the first place.

The question of associating maternity benefits with the insurance scheme was briefly discussed. Dr. MUSGRAVE thought that the existing arrangement sufficed. Dr. W. R. WILSON, on the other hand, was of opinion that this proposal was the best of the whole series, and might result in a great lessening of maternal mortality. It would be a terrible reflection on the medical profession if it did not support some such provision on behalf of the child-bearing population of the country.

The question of maternity benefit as set out in question 7 of the series submitted to local meetings of the profession was answered in the affirmative by 40 votes to 11.

The meeting unanimously approved the somewhat altered procedure suggested in the Memorandum for dealing with official complaints, the proposal to group "additional treatment benefits" with medical benefit, and—with two dissentients—the suggestions as to the future administration of an extended service. Dr. BRACKENBURY briefly explained the greater freedom of the certification rules which were proposed, and these alterations were agreed to unanimously.

## Association Notices.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BATH AND BRISTOL BRANCH.**—A clinical meeting of the Bath and Bristol Branch will be held at Bristol on Wednesday, January 22th.

**EGYPTIAN BRANCH.**—A clinical meeting of the Egyptian Branch will be held in the School of Medicine, Cairo, on Monday, January 26th, when Dr. Catherine Maule will read a paper on the Schick test as done in New York. There will also be a general discussion on diphtheria.

**ESSEX BRANCH: SOUTH ESSEX DIVISION.**—The South Essex Division has arranged a meeting at the Queen's Hotel, Grays, on Tuesday, January 27th, at 8.45 p.m., to discuss the draft Memorandum of Evidence to be presented to the Royal Commission on National Health Insurance.

**KENT BRANCH: DARTFORD DIVISION.**—A special general meeting, called by the Dartford Division, will be held at the Livingstone Hospital, Dartford, on Tuesday, January 27th, at 3 p.m. Business: To consider the draft evidence to be put before the Royal Commission by the British Medical Association (see *BRITISH MEDICAL JOURNAL SUPPLEMENT*, January 3rd); to arrange date of a clinical meeting. All practitioners in the district are asked to make an effort to attend the meeting.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—The Hyde Division is holding a supper d'ansant at Oaklands, Mottram New Road, Hyde, to-day (Friday, January 23rd), at 8.30 p.m.

**LANCASHIRE AND CHESHIRE BRANCH: MANCHESTER DIVISION.**—A joint meeting of the Manchester Division and of the Manchester Medical (and Panel) Committee will be held in the Lecture Hall, Milton Hall, 244, Deansgate, Manchester, to-day (Friday, January 23rd), at 4 p.m., to consider the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance.

**LANCASHIRE AND CHESHIRE BRANCH: MID-CHESHIRE DIVISION.**—The annual meeting of the Mid-Cheshire Division will be held on Wednesday, January 22th, in the Board Room of the Altrincham General Hospital, at 2.30 p.m. Business: Annual Report of the Executive Committee; election of officers for 1925; correspondence, etc. At 3 p.m. there will be a meeting of the medical profession of the Mid-Cheshire area to consider replies to questions on the proposed draft evidence to be placed before the Royal Commission on National Health Insurance.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting will be held in the City Division area on Wednesday, January 22th, at 9.30 p.m., at St. Leonard's, Shoreditch, Church Room, opposite Shoreditch Railway Station, in order to give members and non-members of the Association resident in the area an opportunity of discussing fully the draft Memorandum placed before the Royal Commission. Speakers: Dr. Cardale and Mr. hoped that as many medical meeting, and also carefully study *JOURNAL*, of January 3rd. Any received a copy can obtain on Dr. Ernest A. Worley, 45, Do B the Division will be held at the land Road, on Tuesday, February Edwin Smith, coroner for North-East London, will also appear on some legal relationships of the practitioner.

**METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.**—A meeting of the Kensington Division will be held at the Kensington Town Hall to-day (Friday, January 23rd), at 3.30 p.m., to discuss the evidence it is proposed to place before the Royal Commission on National Health Insurance. It is hoped that all medical men in the Divisional area, whether members of the Association or not, will attend and express their views, as the matters under discussion will affect all practitioners in whatever class of work they are engaged.

**METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.**—A meeting of all practitioners resident in the Marylebone Division, whether members or not, will be held at 8 p.m. on Friday, January 30th, at 11, Chandos Street, Cavendish Square, W.1, to discuss the draft Memorandum of Evidence to the Royal Commission on National Health Insurance. This matter is of extreme importance to all members of the profession, as any contemplated changes will affect consultants and members of hospital staffs, medical officers of health, private practitioners not doing panel work, as well as the panel practitioners.

**METROPOLITAN COUNTIES BRANCH: NORTH MIDDLESEX DIVISION.**—A meeting of all the doctors in the area of the North Middlesex Division will be held in the Fairfax Hall, Portland Gardens, Harringay, on Sunday, January 25th, at 3 p.m., for the further and more detailed consideration of the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance.

**METROPOLITAN COUNTIES BRANCH: WANDSWORTH DIVISION.**—All medical men residing in the boroughs of Wandsworth and Battersea are invited to attend a meeting to be held at 3.30 p.m. to-day (Friday, January 23rd), at Stanley's Restaurant, 237, Lavender Hill, Clapham Junction. Agenda: Explanatory address by the Chairman, Dr. M. G. Biggs; discussion on the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. As the subjects to be discussed are vital to all members of the profession, panel and non-panel practitioners alike, it is hoped that all practitioners will endeavour to be present, as they may not have another opportunity of collectively making known their views.

**MIDLAND BRANCH: DERBY DIVISION.**—A meeting, to which the whole of the medical profession (both members and non-members of the British Medical Association) in the Derbyshire Divisional Area are invited, will be held in the Board Room of the Derbyshire Royal Infirmary to-day (Friday, January 23rd), at 3 p.m., to consider the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. The meeting will be addressed by Dr. G. C. Anderson and Sir Richard Luce, M.P. At the close an opportunity will be given for the asking of questions. It is hoped that the meeting will be well attended in order that the voting on the questions to be submitted may be an expression of the general feeling of practitioners in the area.

**NORTH OF ENGLAND BRANCH: BLYTH DIVISION.**—A meeting of the Blyth Division will be held at the Knight Memorial Hospital, Blyth, on Wednesday, January 28th, at 8 p.m. Business: Election of officers for 1925; consideration of Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance.

**NORTH OF ENGLAND BRANCH: CLEVELAND DIVISION.**—It has been arranged to hold a theatre night at the Opera House, Middlesbrough, on Thursday, January 29th, when *Lilac Time* will be played. After the performance the Chairman of the Division (Dr. Harold Walker) and Miss Walker will be "at home" to members and their friends at Ashleigh, Southfield Road. It is hoped that this, a further effort on the part of the Executive Committee to foster the social side of the Division's activities, will be well supported.

**NORTH OF ENGLAND BRANCH: STOCKTON DIVISION.**—A meeting of the Stockton Division will be held in the Stockton and Thornaby Hospital to-day (Friday, January 23rd), at 8.30 p.m., when the draft Memorandum will be discussed and reported upon.

**NORTHERN COUNTIES OF SCOTLAND BRANCH: INVERNESS DIVISION.**—A meeting of all medical practitioners in the county of Inverness, under the auspices of the Inverness Division and Inverness County and Burgh Local Medical and Panel Committees, will be held on Thursday, January 29th, at 3.30 p.m., in the Palace Hotel, Ness Walk, Inverness. Business: To consider the draft evidence proposed to be submitted by the British Medical Association to the Royal Commission on National Health Insurance, as contained in the *BRITISH MEDICAL JOURNAL SUPPLEMENT* of January 3rd. As a questionnaire thereon will be submitted to the meeting and the answers thereto forwarded to the Medical Secretary of the British Medical Association, being the considered opinion of the medical practitioners in the area, it is hoped that as many practitioners, panel and non-panel, members and non-members, will attend.

**SOUTHERN BRANCH: WINCHESTER DIVISION.**—A special meeting under the joint auspices of the Winchester Division and the Hampshire Local Medical and Panel Committees, and open to all members of the profession, will be held on Sunday, January 25th, in the Oddfellows' Hall, St. George's Street, Winchester, for the purpose of considering the draft Memorandum of Evidence to be submitted to the Royal Commission on National Health Insurance. The chair will be taken by Dr. Williams-Freeman at 2.30 p.m. Arrangements have been made whereby any practitioner living in the southern part of the county may attend a similar meeting, if he finds it more convenient to do so, at Southampton (South Hants Hospital), on Friday, January 23rd, at 8.45 p.m.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—The Swansea Division will hold a medical clinic at the General Hospital on Thursday, January 29th, at 8.15 p.m.

**SOUTH-WESTERN BRANCH: EXETER DIVISION.**—The following course of lectures arranged for the spring of 1925 will be held in the library of the Royal Devon and Exeter Hospital, at 3.30 p.m., on the dates indicated: February 6th, Mr. Norman Lock: Intestinal Obstruction; March 6th, Dr. William Gordon: The Significance of Recent Work in Cardiology; April 3rd, Mr. R. Wayland Smith: Head Injuries; May 1st, Dr. P. A. Roper: Some Principles in Endocrinology. The lectures will be free to all members of the Association.

**SURREY BRANCH: CROYDON DIVISION.**—At the meeting of the Croydon Division to be held at the Croydon General Hospital on Tuesday, January 27th, at 8.30 p.m., Dr. Gordon Holmes, C.M.G., will read a paper on the distinction between functional and organic nervous diseases.

**SURREY BRANCH: GUILDFORD DIVISION.**—A meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, February 5th, at 4 p.m., when Dr. Charles Roberts will read a paper on radiology in general practice. Tea at 3.45 p.m.

**WORCESTERSHIRE AND HEREFORDSHIRE BRANCH: WORCESTER DIVISION.**—A meeting of the Worcester Division will be held at the Worcester General Infirmary at 2.45 p.m. to-day (Friday, January 23rd), to discuss the draft Memorandum of Evidence to be placed before the Royal Commission on National Health Insurance. Non-members are invited to the meeting.

## National Insurance.

### MEMORANDUM OF EVIDENCE TO THE ROYAL COMMISSION.

#### MEETINGS TO BE HELD.

The following meetings have been arranged to consider the draft Memorandum of Evidence to be submitted by the British Medical Association to the Royal Commission on National Health Insurance. Further particulars of many of the meetings will be found in the announcements of forthcoming meetings of Branches and Divisions of the Association (*SUPPLEMENT*, pp. 46-47).

#### North Middlesex Division.

At Fairfax Hall, Portland Gardens, Haringay, N., on Sunday, January 25th, at 3 p.m.

#### City Division.

At St. Leonard's, Shoreditch, Church Room (opposite Railway Station), on Wednesday, January 28th, at 9.30 p.m.

#### Kensington Division.

At Kensington Town Hall, to-day (Friday, January 23rd), at 3.30 p.m.

#### Marylebone Division.

At 11, Chandos Street, Cavendish Square, W.1, on Friday, January 30th, at 8 p.m.

#### Wandsworth Division.

At Stanley's Restaurant, 237, Lavender Hill, Clapham Junction, S.W., to-day (Friday, January 23rd), at 3.30 p.m.

#### Dartford Division.

At the Livingstone Hospital, Dartford, on Tuesday, January 27th, at 3 p.m.

#### South Essex Division.

At Queen's Hotel, Grays, on Tuesday, January 27th, at 8.45 p.m.

#### Winchester Division.

At the Oddfellows' Hall, St. George's Street, Winchester, on Sunday, January 25th, at 2.30 p.m.

#### Derby Division.

In the Board Room of the Derbyshire Royal Infirmary, to-day (Friday, January 23rd), at 3 p.m.

#### Mid-Cheshire Division.

In the Board Room of the Altrincham General Hospital on Wednesday, January 28th, at 3 p.m.

#### Manchester Division.

In the Lecture Hall, Milton Hall, 244, Deansgate, Manchester, to-day (Friday, January 23rd), at 4 p.m.

#### Stockton Division.

At Stockton and Thornaby Hospital, to-day (Friday, January 23rd), at 8.30 p.m.

#### Worcester Division.

At the Worcester General Infirmary to-day (Friday, January 23rd), at 2.45 p.m.

#### Blyth Division.

At the Knight Memorial Hospital, Blyth, on Wednesday, January 28th, at 8 p.m.

#### Inverness Division.

At the Palace Hotel, Ness Walk, Inverness, on Thursday, January 29th, at 3.30 p.m.

#### Berkshire.

A meeting of all practitioners on the Berkshire panel will be held in the library of the Royal Berkshire Hospital on Tuesday, January 27th, at 3 p.m., to discuss the draft Memorandum of Evidence. A speaker from headquarters will attend.

As pointed out in the leading article published in the *JOURNAL* of January 3rd (p. 30), it is of great importance that every medical practitioner, whether serving under the Insurance Act or not, and whether a member of the British Medical Association or not, should attend the meeting in his district. The draft Memorandum of Evidence to be submitted to the Royal Commission was published in the *SUPPLEMENT* of January 3rd, and it is hoped that members attending will take it to the meetings.

### THE ROYAL COMMISSION.

THE thirteenth meeting of the Royal Commission on National Health Insurance was held at the Home Office on January 15th, with Lord Lawrence of Kingsgate in the chair. Mr. Joseph Cave, High Chief Ruler of the Independent Order of Rechabites, and Mr. Jonas P. Illingworth, a director of that Order, were examined on the following subjects: the rates of cash benefits, the deposit contributors' scheme, the administration charges, the extension of medical benefit. Thereafter evidence was heard on behalf of the National Association Friendly Society, represented by Mr. Jonathan Duncan, general secretary, and Mr. Harry Bailey, assistant secretary. Questions as to the age limits for insurance, the size of societies, extension of benefits, workmen's compensation, and dental benefit, were dealt with.

The Conference of Secretaries will be held at 2.30 p.m. on Wednesday, July 22nd, and the Secretaries' Dinner at 6.30 the same evening.

The official Religious Service will be held in the Abbey Church on July 21st at 4.30 p.m.

The Annual Exhibition of surgical appliances, foods, drugs, and books will be opened by the President-Elect on July 21st at 9.30 p.m., and will remain open on July 22nd, 23rd, and 24th.

A Popular Lecture will be delivered by Sir W. H. Bragg, K.B.E., F.R.S., on Friday, July 24th, at 8 p.m.

Saturday, July 25th, will be given up to excursions to places of interest in the neighbourhood.

## THE SECTIONS.

The Scientific Sections will meet from 10 a.m. to 1 p.m. for papers and discussions, and it is hoped that laboratory and clinical demonstrations will be arranged for the afternoons of July 22nd, 23rd, and 24th.

The following Sections will meet on Three Days—Wednesday, Thursday, and Friday, July 22, 23, and 24.

### MEDICINE.

President: The Right Hon. Lord DAWSON OF PENN, G.C.V.O., LL.D., F.R.C.S. (Leeds); M.D., F.R.C.P. (Bath); T. R. F.R.C.P., F.R.S. (London); Professor A. H. ADAM, M.D., F.R.C.P. (Bristol); Professor ADAM PATRICK, M.D., M.R.C.P. (Dundee); W. N. WEST WATSON, M.D. (Bradford).

Honorary Secretaries: F. G. CHANDLER, M.D., M.R.C.P., 1, Park Square West, Portland Place, London, N.W.1; JAMES LINDSAY, M.D., M.R.C.P., 1, The Circus, Bath.

### SURGERY.

President: Sir BERKELEY MOYNIHAN, Bt., K.C.M.G., C.B., M.S., LL.D., F.R.C.S. (Leeds).

Vice-Presidents: A. H. BURGESS, M.B., F.R.C.S. (Manchester); FREDERICK LACE, F.R.C.S. (Bath); H. S. SOUTTAR, C.B.E., M.Ch., F.R.C.S. (London); C. F. WALTERS, F.R.C.S. (Bristol).

Honorary Secretaries: A. DE V. BLATHWAY, M.R.C.S., L.R.C.P., 6, Brock Street, Bath; A. L. FULLER, F.R.C.S.I., 9, Gay Street, Bath; R. M. VICK, O.B.E., M.Chir., F.R.C.S., 152, Harley Street, London, W.1.

### OBSTETRICS AND GYNAECOLOGY.

President: Lady BARRETT, C.B.E., M.D., M.S. (London).

Vice-Presidents: H. S. DAVIDSON, O.B.E., M.B., F.R.C.S. (Edinburgh); EARLEY L. HOLLAND, M.D., F.R.C.P., F.R.C.S. (London); W. P. RAWSON, F.R.C.S. (Bradford); D. C. RAYNER, F.R.C.S. (Bristol).

Honorary Secretaries: J. BRIGHT BANISTER, M.D., M.R.C.P., 39, Harley Street, London, W.1; W. H. DUNCAN, F.R.C.S. (Ed.), 13, Gay Street, Bath.

**PATHOLOGY AND BACTERIOLOGY.**

*President:* Professor J. C. G. LEDINGHAM, C.M.G., D.Sc., M.B., F.R.C.P., F.R.S. (London).

*Vice-Presidents:* J. A. BRAXTON HICKS, M.D., M.R.C.P. (London); Professor E. H. KETTLE, M.D. (Cardiff); RUPERT WATERHOUSE, M.D., M.R.C.P. (Bath).

*Honorary Secretaries:* Lieut.-Colonel JAMES COWAN, M.B., R.A.M.C. (ret.), 44, Combe Park, Bath; C. C. O'KEILL, M.B., M.R.C.P., Wellcome Physiological Research Laboratories, Langley Court, Beckenham, Kent.

**NEUROLOGY AND PSYCHOLOGICAL MEDICINE.**

*President:* Sir MAURICE CRAIG, C.B.E., M.D., F.R.C.P. (London).

*Vice-Presidents:* EDWIN BRANWELL, M.D., F.R.C.P. (London); ARTHUR F. HURST, M.D., F.R.C.P. (Bath); S. A. K. WILSON, M.B., F.R.C.S. (London).

*Honorary Secretaries:* RAY EDWARDS, M.R.C.S., L.R.C.P., 29, Gay Street, Bath; EDWARD MAPOTHER, M.D., M.R.C.P., Maudsley Hospital, Denmark Hill, London, S.E.5.

**THERAPEUTICS (INCLUDING BALNEOLOGY AND RADIO-THERAPY).**

*President:* Professor R. B. WILD, M.D., F.R.C.P. (Chislehurst, Derbyshire).

*Vice-Presidents:* PRESTON KING, M.D. (Bath); W. MITCHELL, M.B., C.M. (Bradford); NATHAN MUTCH, M.D., F.R.C.P. (London).

*Honorary Secretaries:* DOROTHY C. HARR, C.B.E., M.D., M.R.C.P., 1, Bickenhall Mansions, London, W.1; CECIL H. TERRY, M.B., 15, The Circus, Bath.

**LARYNGOLOGY, OTOTOLOGY, AND RHINOLOGY.**

*President:* ARTHUR H. CHEATLE, C.B.E., F.R.C.S. (London).

*Vice-Presidents:* NEIL MACLAY, M.B. (Newcastle-upon-Tyne); IRWIN MOORE, M.B., C.M. (London); SYDNEY R. SCOTT, M.S., F.R.C.S. (London).

*Honorary Secretaries:* H. N. BARNETT, F.R.C.S. (Ed.), 21, The Circus, Bath; R. SCOTT STEVENSON, M.D., 30, New Cavendish Street, London, W.1.

*The following Sections will meet on Two Days.*

**DISEASES OF CHILDREN.**

*President:* ROBERT HUTCHISON, M.D., F.R.C.P. (London).

*Vice-Presidents:* CAREY F. COOMBS, M.D., F.R.C.P. (Bristol); P. T. CRYMBALE, F.R.C.S. (Belfast); CHARLES McNEIL, M.D., F.R.C.P. (Edinburgh); REGINALD H. MILLER, M.D., F.R.C.P. (London).

*Honorary Secretaries:* VINCENT COATES, M.C., M.D., 10, The Circus, Bath; R. A. RAMSAY, M.Ch., F.R.C.S., 123, Gloucester Terrace, Hyde Park, London, W.2.

**OPHTHALMOLOGY.**

*President:* W. MARDON BEAUMONT, M.R.C.S. (Bath).

*Vice-Presidents:* R. WALLACE HENRY, M.D. (Leicester); A. W. ORMOND, C.B.E., F.R.C.S. (London); C. H. WALKER, F.R.C.S. (Bristol).

*Honorary Secretaries:* R. COLLEY, M.B., D.O.M.S., 30, The Circus, Bath; P. G. DOYNE, M.B., F.R.C.S., 8, Harley Street, London, W.1.

**ORTHOPAEDICS.**

(One day being combined with Surgery.)

*President:* Professor E. W. HEY GROVES, M.S., F.R.C.S. (Bristol).

*Vice-Presidents:* NAUGHTON DUNN, M.B., Ch.B. (Birmingham); G. R. GIRDLESTONE, M.B., F.R.C.S. (Oxford); E. MUIRHEAD LITTLE, F.R.C.S. (London).

*Honorary Secretaries:* T. TWISTINGTON HIGGINS, O.B.E., F.R.C.S., 27, Harley Street, London, W.1; J. S. LEVINS, M.C., M.B., 20, Gay Street, Bath.

**PUBLIC MEDICINE.**

*President:* T. EUSTACE HILL, O.B.E., M.B., D.Hy. (Durham).

*Vice-Presidents:* T. W. NAYLOR BARLOW, O.B.E., M.R.C.S., L.R.C.P. (Wallasey); J. F. BLACKETT, M.D. (Bath); W. A. BREND, M.D. (London); S. NOY SCOTT, M.R.C.S., L.R.C.P. (Plymouth).

*Honorary Secretaries:* A. NEVILLE COX, M.D., M.R.C.P., 21, Cornwall Gardens, Preston Park, Brighton; R. E. THOMAS, M.D., 11, Darlington Place, Bath.

*The following Section will meet on One Day.*

**MEDICAL SOCIOLOGY.**

*President:* CHARLES E. S. FLEMING, M.R.C.S., L.R.C.P. (Bradford-on-Avon).

*Vice-Presidents:* J. W. BONE, M.B., C.M. (Luton); WILFRED BUCKLEY, C.B.E. (London); G. P. MALE, M.R.C.V.S. (Reading); E. A. STABLEY, M.B., M.Ch. (London).

*Honorary Secretaries:* C. J. CATFORD, London, S.E.6; C. A. COMBE, Bath.

The Honorary Local General Secretary is Mr. W. G. MEMORON, O.B.E., F.R.C.S. (British Medical Association Committee Rooms, Assembly Rooms, Bath); and the Honorary Assistant Secretary is Dr. R. G. GORDON.

**British Medical Association.****CURRENT NOTES.****Advertisements on the Back of Government Medical Certificates.**

In the SUPPLEMENT of December 27th, 1924, there appeared a letter which was addressed by the Medical Secretary, on the instruction of the Council, to the Minister of Health, taking strong exception to the printing of an advertisement on the back of a medical vaccination certificate, and also urging that in no circumstances should advertisements be placed on the back of any form which has to be filled up by a medical practitioner. The British Medical Association has now been informed that the incident is due to an unfortunate misunderstanding at the Ministry, and a definite assurance has been given that no documents containing forms which have to be filled in by medical practitioners shall in futuro be used as a medium for advertisements.

**The Half-yearly Indexes.**

The usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been published; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association, 429, Strand, W.C.2. Those wishing to receive the indexes regularly as published should intimate this desire.

**Association Notices.****BRANCH AND DIVISION MEETINGS TO BE HELD.**

**BIRMINGHAM BRANCH: COVENTRY DIVISION.**—A meeting of the Coventry Division will be held on Tuesday, February 3rd, at the Coventry and Warwickshire Hospital, at 8.30 p.m. Agenda: Correspondence; annual report and balance sheet; Mr. Bernard Ward on practical points in the treatment of the enlarged prostate.

**BIRMINGHAM BRANCH: NUNSTON AND TAMWORTH DIVISION.**—A clinical and pathological meeting of the Nunston and Tamworth Division will be held at Atherton on Wednesday, February 25th.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—A meeting of the Hyde Division will be held at the Dukinfield Town Hall on Friday, February 6th, when Dr. Alfred Cox, the Medical Secretary, will be present.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, February 10th, at 9.30 p.m., when Dr. Edwin Smith, coroner for North-East London, will read a paper on some legal relationships of the practitioner.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—At the meeting of the Lewisham Division to be held at the Parish Room, 1, St. John's Church, Catford, S.E.6, on Tuesday, February 17th, at 8.45 p.m., a paper will be read by Mr. Frank Cook, F.R.C.S.

**METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.**—A meeting of all practitioners resident in the Marylebone Division, whether members or not, will be held at 8 p.m. to-day (Friday, January 30th), at 11, Chandos Street, Cavendish Square, W.1, to discuss the draft Memorandum of Evidence to the Royal Commission on National Health Insurance. This matter is of extreme importance to all members of the profession, as any contemplated changes will affect consultants and members of hospital staffs, medical officers of health, private practitioners not doing panel work, as well as the panel practitioners.

**METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.**—A meeting of the South Middlesex Division will be held at the St. John's Hospital, Twickenham, on Wednesday, February 25th, at 8.15 p.m., for general business. At 8.30 p.m. Dr. H. C. Corry Mann, O.B.E., will read a paper entitled "Some remarks on dietary during the school age of life."

**METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.**—A meeting of the South-West Essex Division will be held at the Wesleyan Church School Rooms, High Road, Leyton, on Tuesday, February 3rd, at 3.30 p.m. At 4.15 p.m., after the completion of the ordinary business, Mr. W. Ibbotson, F.R.C.S., will read a paper on catarrhs of the nasopharynx and its ramifications. Tea will be served at 3.15.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A dinner will be held at the Comedy Restaurant, Pantons Street, Haymarket, S.W.1, on Sunday, February 15th, at 7 p.m. Tickets can be obtained from Dr. W. Lock, 45, Church Road, N.W.10.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—A clinical and pathological meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, February 13th, at 8.30 p.m., when there will be a demonstration of cases.

**NORTH OF ENGLAND BRANCH: SUNDERLAND DIVISION.**—The annual meeting of the Sunderland Division will be held at 48, John Street, Sunderland, at 8.15 p.m., to-day (Friday, January 30th).

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—At the meeting of the Swansea Division to be held at the General Hospital, Swansea, on Thursday, February 12th, at 8.15 p.m., a paper will be read by Dr. Daniel E. Evans.

**SOUTH-WESTERN BRANCH: EXETER DIVISION.**—The following course of lectures arranged for the spring of 1925 will be held in the library of the Royal Devon and Exeter Hospital, at 3.30 p.m., on the dates indicated: February 6th, Mr. Norman Lock: Intestinal Obstruction; March 6th, Dr. William Gordon: The Significance of Recent Work in Cardiology; April 3rd, Mr. R. Wayland Smith: Head Injuries; May 1st, Dr. F. A. Roper: Some Principles in Endocrinology. The lectures will be free to all members of the Association.

**STAFFORDSHIRE BRANCH: SOUTH STAFFORDSHIRE DIVISION.**—The fourth meeting of the session 1924-25 of the South Staffordshire Division will be held at the Victoria Hotel, Wolverhampton, on Tuesday, February 3rd, at 8.15 p.m. Supper, 3s. 6d. each (exclusive of wines), will be served at 8.30 prompt. Mr. H. H. Joy, K.C., will deliver a British Medical Association Lecture on the medical witness. Members of other Divisions will be welcome. Those intending to be present are asked to notify the chairman (Dr. J. H. Sheldon, 261, Tettenhall Road, Wolverhampton), so that arrangements can be made.

**SURREY BRANCH: GUILDFORD DIVISION.**—A meeting of the Guildford Division will be held at the Royal Surrey County Hospital, Guildford, on Thursday, February 5th, at 4 p.m., when Dr. Charles Roberts will read a paper on radiology in general practice. Tea at 3.45 p.m.

## Meetings of Branches and Divisions.

### BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.

A MEETING of the Nuneaton and Tamworth Division was held at Tamworth General Hospital on January 22nd. The report of the Division for the past year was presented and approved. Dr. K. D. WILKINSON (Birmingham) read a paper on "cardiac irregularity," which was illustrated by anatomical and pathological specimens, charts, and an ink polygraph. The lecturer, after giving a very clear account of the normal mechanism of the heart, dealt with the pathology of the various forms of cardiac irregularity and with modern methods of diagnosis and treatment. The paper was very greatly appreciated.

### BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.

A MEETING of the Dumfries and Galloway Division was held in the Royal Infirmary, Dumfries, on January 22nd, when Dr. P. M. KERR, vice-chairman, presided. The annual report was adopted and also Minute 41 of the Representative Body concerning the fee for lecturers to ambulance classes. The programme for the current year was discussed, and it was decided to hold a social meeting in the summer, either in Wigtown or Kirkcudbrightshire, and to hold clinical meetings when convenient in all three shires, and to arrange for papers.

An animated discussion took place on the report of the Scottish Departmental Committee on puerperal morbidity, and the discussion was adjourned until the next meeting, the Secretary being instructed in the meantime to circulate copies of the report.

The meeting then resolved itself into a meeting of medical practitioners of Dumfriesshire and Dumfries and Maxwelltown, two non-members being present, to consider the draft evidence to be placed before the Royal Commission on National Health Insurance. Dr. P. M. KERR was called to preside, and Dr. BRYSON, a member of the Scottish Rural Subcommittee, was present and explained the various points as they arose.

### EGYPTIAN BRANCH.

A GENERAL meeting of the Egyptian Branch was held at Cairo on December 30th, 1924. Mr. MADNEX, having read the minutes of the inaugural meeting of the Branch in January, 1924, and of the Branch Council in November, 1924, stated the arrangements made regarding the clerical work of the Branch, which were approved. The proposed new Branch rules were discussed and, after certain modifications, adopted.

In response to the invitation to attend the Annual Meeting of the Association at Bath in July, 1925, Mr. MADNEX agreed to attend to represent the Branch. The vacancies on the Branch Council caused by the departure of various members were filled. A suggestion put forward by Dr. BROWN that a clinical meeting would be of increasing interest to members was warmly supported.

### GLOUCESTERSHIRE BRANCH.

A MEETING of the Gloucestershire Branch was held at the Royal Infirmary, Gloucester, on December 11th, 1924, with the President, Dr. J. MIDDLETON MARTIN, in the chair. Dr. D. E. FISLAY, senior physician to the Infirmary, showed and discussed the following nine cases:

1. A boy with lupus vulgaris of the thigh, following a minor injury two years previously.

2. A case of extensive and inveterate seborrhoeic eczema in a child for which numerous remedies had been tried, the most successful being salicylic acid. Dr. J. Goss suggested that in the absence of improvement from persistent skin-popping x rays should be tried. Dr. H. C. TERRY laid stress on the possibility of infection of the skin of the child from the scalp of the mother.

3. A man with lupus erythematosus of the face and scalp. The condition had existed for four years and had received many varieties of treatment, including ether soap, calamine lotion, arsenical paint, carbon dioxide snow, and vaccine from his enucleated tonsils. Dr. ALMAN POWELL considered that intestinal stasis should always be kept in mind in such cases. Dr. J. Goss found that x-ray treatment did good, but that the resulting disfigurement was rather worse than the original condition.

4. A child with urticaria pigmentosa existing since the age of 4 months, and for which a year's ineffective treatment with hydrarg. c. crel. had been given before Dr. FISLAY saw the case. This helped to distinguish it from a syphilitic lesion, which it resembled. Belladonna and atropine had been found of some value.

5. A man with chronic dermatitis with ulceration of the foot and leg. Dr. C. V. KNIGHT suggested trying a plaster case owing to the possibility of its being an artefact. Dr. FISLAY said the condition cleared up under Unna's paste, but the patient took it off as he said it was uncomfortable, and the persistence of the condition was probably due to interference by the man.

6. A case of exophthalmic goitre with definite symptoms in a young man closely following an accident. There was no improvement whatever after six weeks' rest and treatment, and an injection of 5 units of insulin was tried. Within two hours the pulse, which had been consistently at about 130 per minute, fell to 85 and remained down for two weeks. Then the pulse rate began to creep up and was now as rapid as before. Insulin was being tried again, but with no conspicuous success. There was nothing in the blood sugar condition to raise any expectation of improvement from insulin, yet the immediate change after the first injection was dramatic.

7. A boy with encephalitis lethargica. The first symptom was delayed sleep and constant movements of the legs. Next day there was headache and the boy appeared to be silly. Sleepiness and paralysis of the left sixth cranial nerve followed. The boy was now much improved. Dr. J. G. SOUTAR agreed this was a definite case of the disease, but thought that encephalitis was over-diagnosed at the present time. In his experience sequelae were marked when the illness began with a high temperature. In children it was a most damaging disease, frequently leading to moral degeneration. It was noticeable that comparatively few cases were followed by certifiable insanity. Dr. TERRY had recently had a case in a boy about the same age in which the onset in its details exactly corresponded to the one shown.

8. A young man with the Parkinsonian syndrome following encephalitis. This case began with acute mania, but diplopia was found. The excitement disappeared in a week under paraldehyde. In two weeks the patient was almost comatose; within six weeks the syndrome was established. Dr. SOUTAR remarked that the acute mental stage was unusual and that it was also unusual for the Parkinsonian syndrome to follow at once the acute stage; one might wait several years before signs appeared. He emphasized rigidity in some group of muscles as the characteristic early sign.

9. A man, aged 31, first admitted to hospital a year ago with a diagnosis of typhoid as he had been nursing that disease. On admission, nine weeks after the onset of the illness with delirium, he looked very ill, was wasted, and had retraction of the head, but no cranial paresis or Kernig's sign. A lumbar puncture was performed, and the cerebro-spinal fluid gave a negative Wassermann reaction, but showed some lymphocytosis and excess of globulin. His blood gave a negative Widal reaction. He left the hospital convalescent, but returned in May with weakness of the legs, and he developed what appeared to be typical spastic paraplegia. His Widal reaction was then positive, and his Wassermann still negative. It did not seem possible to exclude encephalitis in such a case.

### KENYA BRANCH.

A MEETING of the Kenya Branch was held at the Native Civil Hospital, Nairobi, on November 5th, 1924, when the President, Dr. A. JEX-BLAKE, took the chair.

The terms of reference of the East African Parliamentary Commission were discussed. It was pointed out that the Commission had so far been afforded little opportunity of seeing the work carried out by the public health service in the colony, and the following resolution was, on the motion of Dr. WILSON, seconded by Dr. PATERSON, carried unanimously:

That this meeting notes with regret that the programme as published affords the Parliamentary Commission now in Kenya no adequate opportunity of seeing the work of the public health services of the country and the Government medical activities generally, although provision has been made for visiting all mission stations where medical work is being carried out. In particular it regrets that the tour in Kavirondo has not included any opportunity for the Commission to become acquainted with the important public health work in those districts. It trusts that full effect will be given to the assurance of His Excellency the Governor, as communicated to the meeting by Dr. GILKS, that this omission will be rectified during the remainder of the tour. The meeting resolves that a copy of this resolution be sent to the Honourable Colonial Secretary and to each of the members of the Commission.

On the motion of Dr. BUREITT, seconded by Dr. MACKINNON, it was also unanimously resolved:

That the members of the Kenya Branch of the British Medical Association would be glad to meet the members of the East African Parliamentary Commission should they wish it, and to answer any questions of medical or public health interest in connexion with the Commission's terms of reference.

### METROPOLITAN COUNTIES BRANCH: CAMBERWELL DIVISION.

A MEETING of the Camberwell Division was held at the Maudsley Hospital, Denmark Hill, on January 20th, when Dr. R. KING BROWN was in the chair. Members of the Lambeth Division also attended by invitation. Dr. EDWARD MORTIMER, medical superintendent of the hospital, gave an address on the present provision

for the treatment of mental disorder, and suggested improvements. A suggestive and illuminating address was listened to with great interest, particularly because of the proposed early amendment of the Lunacy Act. Some discussion took place, and a number of questions were answered by the lecturer. The meeting closed with a hearty vote of thanks to Dr. Mapother.

#### METROPOLITAN COUNTIES BRANCH: MARYLEBONE DIVISION.

A MEETING called by the Marylebone Division to discuss the draft evidence proposed to be submitted to the Royal Commission on National Health Insurance was held at 11, Chandos Street, on January 14th, when Mr. C. E. WALLIS was in the chair. On the motion of Dr. C. O. HAWTHORNE the meeting decided to confine itself in the first instance to answer the questions in document D.12, discussion on general points to come later. It then proceeded to discuss and to answer the questions in order. The meeting was not in favour of including dependants. The replies in all cases were the outcome of large proportional votes. Among those taking part in the discussion were Dr. C. O. HAWTHORNE, MESSRS. MCADAM ECCLES, BISHOP HARMAN, H. S. SOUTAR, and BEDDOES, DRs. HALLS-DALLY, ADAMS, SPURGIN, and GOULET.

#### METROPOLITAN COUNTIES BRANCH: STRATFORD DIVISION.

A SPECIAL meeting of the Stratford Division, which includes the insurance areas of West Ham, East Ham, and a portion of Essex, was held at the Educational Offices, Stratford, on January 20th, to consider the draft Memorandum of Evidence to be placed before the Royal Commission. Dr. G. F. WILSON was in the chair, and after a long discussion the various resolutions were put to the meeting.

The following resolution referring to the appointment of an assistant school medical officer for the county borough of West Ham was further put to the meeting and carried unanimously by the members of the Division present:

"That in the opinion of the Stratford Division no medical practitioner, within the area of the Division, should apply for an appointment as assistant school medical officer under the county borough of West Ham at a lower rate of remuneration than 1600 per annum, exclusive of travelling and other official expenses, or continue to hold any such appointment made after July 23rd, 1923, at a lower rate of remuneration than that stated above."

The opportunity was taken of making a presentation to Dr. Charles Sanders on his retirement after thirty-seven years' service as medical officer of health for West Ham. The presentation took the form of a pair of binoculars, a silver breakfast dish, and a tortoiseshell manicure set in a tortoiseshell case for Mrs. Sanders. The presentation was made by Dr. Wilson, and Dr. SANDERS, in reply, expressed his thanks for the appreciation of his colleagues.

#### NORTH LANCASHIRE AND SOUTH WESTMORLAND BRANCH: FURNESS DIVISION.

A MEETING, to which all medical men in the Furness area were invited, was held at the Criterion Restaurant, Barrow, on January 14th, when Dr. FAWCETT was in the chair. Dr. Cox, the Medical Secretary, attended to explain the draft Memorandum of Evidence to be put before the Royal Commission on National Health Insurance. The Memorandum was taken in sections, Dr. Cox first making a short explanation, questions and comments being made next, and then the questions dealing with that section were put to the vote.

On the motion of Dr. THOMPSON, seconded by Dr. CARSON, a vote of thanks to Dr. Cox was carried with applause. In the evening a dinner was held at the same place.

#### SOUTH WALES AND MONMOUTHSHIRE BRANCH.

The winter meeting of the South Wales and Monmouthshire Branch was held in the Council Chamber, Town Hall, Llanelly, on January 21st, when the Vice-President, Mr. R. J. COULTER, was in the chair. After the ordinary business of the meeting had been transacted the remainder of the meeting was devoted to papers and clinical cases.

Mr. T. E. HAMMOND (Cardiff) read a paper on hæmaturia, and dealt in detail with the various causes of the symptoms and signs. Specimens of urine were shown. He stated that in only 30 per cent. of cases were clinical signs present, and emphasized the importance of a cystoscopic examination in every case. The examination and interpretation of the findings should be performed by one who was well experienced in the work.

Dr. T. R. DAVIES read a short paper on "A New System of Anatomy," based on the book with that title by James Drake, M.D., published in 1707. The descriptions of the circulation, heart innervation, and respiration were read. The book contained an accurate account of the intrinsic muscles of the larynx.

Dr. J. J. HEALY (Llanelly) read a paper on the diagnosis of glaucoma, describing the types, modes of onset, clinical symptoms, and of emergency. The operation of trephining was described, and clinical cases shown. Dr. Healy demonstrated a specimen of melanotic sarcoma of the ciliary body; and, jointly with Dr. A. H. D. SMITH, showed a case of bilateral oculomotor nerve paralysis in a boy who gave a positive Wassermann reaction.

Dr. G. V. DAVIES showed cases of: (a) deep adenoma of the thyroid gland removed by open operation which completely relieved the dysphagia and dyspnoea; (b) two fractures of the right forearm within eighteen months, treated by open operation and Thomas's splint without pegs, wires, or plates; the anatomical and functional results were good.

Dr. A. H. D. SMITH showed a septic knee-joint, treated by

Kocher's open operation, without drainage, and an extensive burn of the leg treated with amblime.

Dr. T. R. DAVIES (Llanelly) showed two cases of dactylitis in infants, illustrated with skiagrams; also a case for diagnosis—a girl, aged 10, with enlarged liver and spleen and a slight lymphocytosis.

#### SOUTH WALES AND MONMOUTHSHIRE BRANCH: CARDIFF DIVISION.

A WELL attended clinical meeting was held at Glam-Ely Tuberculosis Hospital (one of the institutions maintained under the King Edward VII Welsh National Memorial Association) on December 3rd, 1924. Dr. ALEXANDER BROWNLEE, the medical superintendent, gave an instructive demonstration on artificial pneumothorax in the treatment of pulmonary tuberculosis. An excellent series of lantern slides was shown depicting the lung conditions under treatment, accompanied by their respective temperature and pulse charts. Professor LYLE CUSIMANS gave a synopsis of the rationale of the pneumothorax treatment.

A hearty vote of thanks was accorded Dr. Brownlee for his kind invitation, and appreciation was expressed for the sturdy work which was being done in the fight against tuberculosis.

#### YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.

THE fourth of the seven monthly lecture meetings arranged by the Wakefield, Pontefract, and Castleford Division for the present winter session was held at Wakefield on January 15th, under the chairmanship of Dr. WILLIAM STEVEN (Featherstone). An address on changes in reflexes in health and disease was given by Dr. J. LE F. BURROW (Leeds), who, after lucidly describing the anatomical and physiological bases of reflexes, gave an interesting practical demonstration of the methods of their elicitation and their interpretation. A hearty vote of thanks was accorded to Dr. Burrow for his most useful address.

## THE EVIDENCE TO THE ROYAL COMMISSION.

### MEETING OF THE MEDICAL PROFESSION IN EDINBURGH.

A MEETING of the medical profession in Edinburgh, called at the instance of the local Division of the British Medical Association, was held in the Hall of the Royal College of Surgeons on January 20th to discuss the draft Memorandum of Evidence proposed to be placed before the Royal Commission on National Health Insurance (SUPPLEMENT, January 3rd (pp. 1-8)). The chair was taken by Sir DAVID WALLACE, K.B.E., C.M.G., F.R.C.S., who was supported by Dr. G. Keppie Paterson, Chairman of the Edinburgh and Leith Division, and by Dr. J. R. Drever, Scottish Medical Secretary of the Association.

Sir DAVID WALLACE, in his opening remarks, said that the Committee of the British Medical Association, which had for some time been considering the future of national health insurance and its relationship to the medical profession, was very representative, consisting both of those working under the National Health Insurance Act and of those who were not working under that Act, and he thought that the draft Memorandum had been drawn up in a very careful manner and that its statements were couched in the most moderate terms. He then called the attention of the meeting to the questions asked in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of January 3rd (p. 9), and requested that answers should be in the affirmative or in the negative, as he did not think that suggestions containing alterations and additions would be of much help. The inclusion of dependants for purposes of medical treatment was discussed, and in view of the fact that the subject of limiting the medical benefit to persons below a certain income level was so involved, it was decided that it would be better meantime to recommend the exclusion of dependants altogether from the operation of national health insurance; the questions as to their inclusion were, therefore, answered by the meeting in the negative. The second question as to whether, if dependants should be included, it would be essential to secure provisions for lessening the work, was answered unanimously in the affirmative.

With regard to the inclusion of poor persons not under contract of service, the meeting was equally divided, and the Chairman refrained from giving a casting vote. The meeting was in favour of the inclusion in the national health insurance scheme of the class of persons at present attended under the Poor Law. With regard to the extension of the present service to specialists and consultants at some convenient time, the meeting unanimously agreed that this should be done, and, further, that this extension of specialist and consultant services should take precedence of the inclusion of dependants. As regarded the inclusion of attendance at confinements and during the puerperal period, together with special examination and supervision during pregnancy, being brought within the scope

of the national health insurance scheme, it was pointed out that any practitioner, should he not wish to do maternity work, would be free to refuse, and that he might also decline to attend the wife of an insured person on his list, while, on the other hand, those who were specially interested in maternity work, even if they were not doing other insurance work, might engage in this branch of practice and receive payment from the State for doing so. This question was accordingly answered in the affirmative. Approval was given unanimously to the questions asked regarding procedure for official complaints and the grouping of additional treatment benefits with medical benefit and their removal from the control of approved societies. The meeting agreed with the suggestions of the Association regarding the future administration of a national health insurance service in conjunction with the other health services of the country.

At the conclusion of the meeting a resolution was adopted cordially approving of paragraph 2 of the draft Memorandum regarding the directions other than a national health insurance scheme in which expenditure might be made to produce an even more satisfactory return in regard to the health of the community. The meeting terminated with a vote of thanks to the Chairman and to the College of Surgeons for the use of its hall.

#### NORTH DEVON.

A MEETING of the local medical profession was held at Barnstaple on January 21st to discuss the Memorandum of Evidence to be presented to the Royal Commission on National Health Insurance. The meeting was called by the North Devon Division of the British Medical Association. In framing answers to the questions set out in Document D. 12 (SUPPLEMENT, January 3rd, p. 9) particular attention was devoted to question 11, regarding certification:

"Does the meeting agree with the alterations in the rules of certification proposed in paragraph 51? If not, state alternative suggestions."

The meeting decided that paragraphs 50 and 51 of the draft Memorandum of Evidence (Document D. 11, pp. 6, 7) ought to be strengthened, on the ground that as they stood these paragraphs did not sufficiently express the feelings of many medical men, especially those engaged in rural practice. Remembering the heavy burden imposed on practitioners by the certification rules, the meeting considered that these rules constituted one of the most important reasons for any unpopularity there might be for service under the Insurance Acts. On the proposal of Dr. H. C. JONAS, the following amendments to paragraphs 50 and 51 were unanimously approved:

#### ALTERNATIVE SUGGESTIONS REGARDING CERTIFICATION.

##### Paragraph 50.

Page 6, line 3.—To insert the word "medical" after the word "false."

Page 7, line 1.—To insert a fullstop after the word "rules"; and to delete the words "which, since they were in force, should have been strictly obeyed."

After the fullstop after "rules" to insert the following sentence: "Practically all these instances of laxity are concerned with infringements of the non-medical part of the certificate."

Page 7, line 3.—To substitute the word "impossible" for the word "difficult."

Last line of the paragraph.—To delete the last five words and to insert a fullstop after the word "accurately."

##### Paragraph 51.

To commence the paragraph with the following words: "The present certification rules impose a duty on the practitioner of visiting a patient at stated intervals, quite irrespective of the medical necessities of the case, and of giving certificates 'on the terms,' on the occasions, and in the manner required—in other words of performing certain administrative duties on behalf of the approved societies which are properly those of a sick visitor, and not of a medical practitioner. The slightest breach of these rules has been followed by severe penalties, though the certificate is in fact a statement of the facts of the case, and has a medical nat y false or misleading of duties and restrictions prevent many—often of the highest professional skill—from taking part in National Health Insurance work. Unnecessary visits for the purpose only of certification are demoralising both to the patient and practitioner; they tend at all times to perfunctory work, and in times of stress to the omission of visits which are of far more urgent in country practice, where the time involved is obviously much greater. Notes on the certificates and letters of explanation are extremely irksome and distracting to a busy doctor, and it is not too much to say that in rural practice at least the rules cannot be properly observed, and that technical breaches are committed and passed over by all concerned. It must, however, be recognized that it is of the greatest importance that the highest standard in a truly medical certificate should be maintained and . . ."

Line 2.—To delete the words "would conduce to" and substitute the words "are necessary to secure."

Line 6.—After the word "benefits" to insert the following sentence: "The most important point in which Insurance Service compares unfavourably with non-panel practice is that these rules impose on the practitioner duties of certifying matters of fact apart from a purely medical opinion; and that any inaccuracy on this respect—e.g., a question of dates—is regarded by the Insurance Committees, the Ministry, and, worst of all, the General Medical Council as a breach of professional accuracy."

Line 15.—To insert a fullstop after the word "present," to delete all to the end of (a) and to substitute the following: "It is suggested that (a) All intermediate certificates shall be purely medical certificates of the form, 'I hereby certify that . . . is suffering from . . . and is unable to work."

Dated . . . Signed . . ."

## National Insurance.

### THE ROYAL COMMISSION.

THE fourteenth meeting of the Royal Commission on National Health Insurance was held at the Home Office on January 22nd, Lord Lawrence of Kingsgate in the chair. Evidence was received from three miners' societies: the Scottish Miners' Federation Approved Society (Mr. James Gold), the Lancashire and Cheshire Miners' Permanent Approved Society (Mr. D. Shaw), and the Lancashire and Cheshire Miners' Federation Approved Society (Mr. Lee Shaw). The special difficulties arising in societies composed wholly or largely of miners were represented by these witnesses—in particular the inability to give additional benefits owing to the unavoidable heavy expenditure on normal benefits for those engaged in the mining industry.

Proof copies of oral evidence given at the meeting of January 8th may be obtained from H.M. Stationery Office, Adelphi House, Kingsway, W.C.2, on remittance of cost (1s. 6d.) and postage.

### LONDON INSURANCE COMMITTEE.

#### Chairmanship of the Medical Service Subcommittee.

A LONG-STANDING dispute which has not previously found expression in open meeting came before the Committee on January 22nd with regard to the chairmanship of the Medical Service Subcommittee. This position has been held for the last seven years by Mr. David Davis, D.L., J.P. The medical members of the Committee are Dr. R. L. Bell and Dr. W. C. Gooden (representing the Panel Committee), and Dr. K. McFadyen (representing the Local Medical Committee), and there are three lay persons representing the Insurance Committee.

The Chairman of the Insurance Committee (Mr. W. J. Wightman) stated that the Medical Service Subcommittee had not been able to perform its duties owing to the abstention of the medical representatives from the last four meetings summoned, so that the subcommittee was unable to form a quorum. The medical representatives had declared that they would neither attend the meetings of the Medical Service Subcommittee nor resign their membership thereon while Mr. Davis remained chairman. During the seven years of his chairmanship Mr. Davis had discharged his onerous duties to the satisfaction of the Insurance Committee. In that period 635 cases had been considered, and only 8 decisions had been upset on appeal. Up to November last the chairman had had to exercise his casting vote only on ten occasions; on eight of these occasions he voted against the view of the medical members. Five of these cases went to appeal, and in only one case was the appeal allowed. Some opposition was expressed to Mr. Davis's continuance in office in 1923, and in 1924 the Panel Committee passed a resolution to the effect that the continuance of Mr. Davis in the chairmanship was not acceptable to that body, and instructed its representatives to oppose his re-election. Mr. Davis was the choice of the neutral members. The Ministry of Health, to which the Panel Committee had appealed, asked the chairman of the Insurance Committee (himself) to consider the problem, and he was bound to report that he found himself utterly unable to find any tangible reason for compliance with the demands of the medical representatives. Later a deputation from the Insurance Committee waited on the Minister of Health and made strong representations against the insistence of the doctors to terminate the chairmanship of Mr. Davis. The attitude of the Ministry appeared to be that the Medical Service Subcommittee could only properly function when the chairman was acceptable to all its constituent factors. The deputation strongly disagreed with this interpretation, and declined to advise the resignation of Mr. Davis. The peculiar duties of the subcommittee as a tribunal on cases of complaint against the medical service placed a grave responsibility upon the medical representatives, for these representatives were assuming an attitude which prevented complaints against members of their own profession from being heard, and an intolerable position was created.

Dr. Cardale said that the time was inopportune for making a long statement from the point of view of the medical members. A very difficult and serious situation had arisen. At present, as chairman of the Panel Committee, he was trying to discover whether there was not some way out of the impasse, and to enter into controversy at the moment would mean only angry words and personalities.

Mr. J. Skinner moved and Mr. H. Mills seconded a resolution:

"That this Committee, whilst recognizing that the medical representatives have abstained from the Medical Service Subcommittee in order to draw attention to their views, urges them to fulfil their constitutional obligations or to give place to such other members of the medical profession as are prepared to serve."

Sir Thomas Neill, in supporting, said that members of the medical profession were in their infancy in matters of business; they were the most incompetent business people he had ever met.

Dr. C. H. Pring protested against the stifling of discussion in order to avoid personalities. He declared the demand made by the medical members of the subcommittee to be monstrous. The key to the situation was the fact that the London Panel Committee was practically the Medical Practitioners' Union, which was an ordinary trade union. The methods introduced by the medical members of this subcommittee were those of a trade union. Those members appeared, not as administrators of justice, but as advocates for the practitioners whose conduct was being investigated. Practitioners against whom notice of complaint was given were urged to apply for advice from the officials of the Panel Committee beforehand, and it was the representatives of the Panel Committee who eventually "tried" them. Dr. Cardale strongly protested against these statements, but Dr. Pring said that he had been himself a member of the Panel Committee and was well aware of the procedure. Dr. Pring went on to say that the medical members of the subcommittee had formed a conspiracy against their neutral chairman because on certain occasions he had given his casting vote against them.

Mr. Rockliff charged the Panel Committee with influencing the free judgement of the medical members of the subcommittee, and pointed out the distressing nature of the position when insured persons were daily forwarding complaints of the treatment they were getting, and the doctors would not lend a hand to decide on the complaints.

The Chairman said that the Insurance Committee could take no action to compel the medical members to attend, and the matter was now in the hands of the Ministry of Health.

Mr. Skinner's resolution was carried without dissent.

*Practitioners' Appeals Dismissed.*—It was reported that in five cases in which practitioners appealed to the Minister of Health against the decision of the Insurance Committee in the matter of their alleged breaches of the regulations, the Minister had in every case dismissed the appeal, and in all cases except one had imposed fines varying from £5 to £50, and had ordered the practitioner to pay the costs of the Committee in a sum not exceeding £5. In the remaining case the Minister had deferred a decision on the question of a fine until after the result of some pending litigation with regard to the case.

*The Royal Commission.*—Consideration had previously been given by the Committee and other bodies concerned to the question whether, having regard to the peculiar position which London occupies in the matter of insurance administration, it might be possible for the Insurance Committee and the Panel and Pharmaceutical Committees to present a joint case to the Royal Commission. It was now reported, however, that it appeared, after some preliminary conferences, that the Panel and Pharmaceutical Committees, while anxious to assist the Insurance Committee, could not very well dissociate themselves from the evidence to be given on behalf of the medical profession and the pharmaceutical profession respectively. Therefore it had been decided that the Insurance Committee should give evidence in its own behalf.

*Surgery Accommodation.*—A joint report was presented by Mr. J. Skinner, Chairman of the Medical Benefit Subcommittee, and Dr. C. L. Batteson, Secretary of the Panel Committee, with regard to their visits to the surgeries of certain practitioners. Since the former report visits had been paid to the surgeries of forty-five practitioners in all parts of London, and in the majority of cases it was found that the accommodation provided was satisfactory, having regard to the circumstances of the practice. In a few cases in which alterations were suggested by the Committee's representatives in order to provide additional waiting-room accommodation, the practitioners concerned were willing to adopt and carry out the suggestions made.

#### LONDON PANEL COMMITTEE.

*Constitution of the Committee.*—At the meeting of the London Panel Committee on January 20th Dr. R. G. Chase moved that the Committee appoint a section to consider necessary alterations in the rules, statutory or otherwise, affecting the constitution and work of the Committee, with a view to making service on the Committee more interesting and therefore more attractive to the ordinary medical practitioner in London, and also to consider the question of the remuneration of members as at present in force

in other panel committees. It was agreed to set up such a section, and Drs. M. B. Bayly, J. Collar, W. H. Palmer, and J. E. Stratton, with the Chairman and Vice-Chairman of the Committee, Dr. Cardale and Dr. Gregg, were appointed members.

*A Prescribing Survey.*—A subcommittee reported that it had had under consideration the question of the advisability of the addition to the drug tariff of pills of 5 grains in every case in which 5-grain pills at present appear. During the present prescribing survey it had become apparent that 5-grain pills were very generally ordered by practitioners, and as 5-grain pills carried an extra dispensing fee, such ordering would seem to be one of the factors tending to increase the drug bill. A recommendation to this effect was agreed to. A further result of the prescribing survey is that it has been shown that a considerable wastage of medicine is at present caused by the use of medicine bottles lacking correct graduation in respect of the doses to be taken. It was agreed to inform the Ministry of Health to this effect.

## Correspondence.

### *Psychology and the Panel.*

SIR,—Health insurance differs from all other forms of insurance in that psychology takes a part. Consciously or unconsciously, it enters into the successful treatment of a large proportion of patients, and it therefore should be given prominent consideration when laying the foundation of health insurance.

It is my humble opinion that the present system of national health insurance fundamentally interferes with the successful application of psychological treatment. Some of my panel patients would never be cured by their panel doctor, and, on the other hand, some of my "best cures" have been among panel patients whom I have treated privately, as they were on the lists of other doctors—as good as myself or better.

At this time of transition I would plead, not for a patching up of the present system, but for a system by which the poorer classes were compelled to set aside regularly part of their earnings to pay medical and maintenance expenses when they arose.—I am, etc.

Cheltenham, Jan. 13th.

M. J. ROCHE, M.B.

### *State Insurance and the Medical Profession.*

SIR,—In view of the evidence which it is proposed shall be placed by the British Medical Association before the Royal Commission on National Health Insurance in the near future, perhaps you will be kind enough to publish the views of one who has had experience of the panel system from its inception.

When the German scheme was first introduced the profession generally viewed it with distrust, and rightly so. It was too full of pinpricks and all the hundred and one restrictions so foreign to English ideas. And now, in 1925, we look back and ask ourselves, What has it done for us, and what has it done for the public as a whole? I venture to say—and there are many who hold the same view—that it has been a failure.

In reading many of the articles in the *BRITISH MEDICAL JOURNAL* and other periodicals, it has struck me more than once that they have been written by men with only a second-hand knowledge of their subject; and it is obvious to me that nowadays, more so than ever, it is easier to evade the truth than speak it. Take, for instance, the question of a small panel. How can we expect a legitimate return for work done? In one case alone it worked out to the tune of 12s. 11d. for over fifty consultations and prescriptions—a truly wonderful return for the thought and time expended over the cases; and there are many such examples.

And now we are in 1925. As a friend of mine said to me the other day, "What has the British Medical Association done for us? I think it has let us down." No, I would not go so far as that; but I do think it has shown much weakness where we looked for strength. Take the question of "gross panels." Have all these been achieved fairly? I am sorry to say many have not, and if the matter of canvassing had been looked into strange disclosures would doubtless have resulted.

It is necessary to mention these facts as they strike at the very root of things and help us to look them squarely in the face. The "moral" of the profession, too, has deteriorated at least 50 per cent. since the advent of State insurance, and self-respect, as regards both the profession and public, has been lowered, not raised. I could quote instance upon instance in support of what I say, and, further, I am voicing the opinions of others. Wherever the State creeps in trouble usually follows, but it is with regard to the treatment of sickness that the State should exercise extraordinary care.

We charge a fee commensurate with the kind of ease we are attending—or at least I hope we do—but the State does not recognize such a thing; it tries to beat us down. The question of life and death is a matter of words only.

A scheme such as this is to-day is not one to attract the best of the profession. It antagonizes, does not encourage. Take the subject of medical referees. What effect has that produced in the profession? Again—let us have the truth—a

feeling of opposition, a feeling of indifference. You say this is untrue, but if you would take the trouble to find out the number of cases in which the general practitioner has failed to meet the referee you would doubtless change your opinion. From my point of view, any case requiring a second opinion (and it is chiefly the societies who are down on the profession) should be settled locally; and further, all referees should be general practitioners, or at least have been in practice as such.

I am sorry to be obliged to write in this strain, but in view of the future, and what has been my experience of the Act in the past, I feel it my duty to speak the bare truth, which seems to be evaded by most writers in the JOURNAL.—I am, etc.,

Canford Cliffs, Dorset, Jan. 14th.

FRANCIS G. BENNETT.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

SURGEON COMMANDERS J. McDONALD and J. Martin are placed on the retired list, with the rank of Surgeon Captain.

Surgeon Commanders J. H. McDowall to the *Gleopatra*, additional, temporary; E. L. Markham, O.B.E., to the *Zece*; Holton, O.B.E., to the *Virid*, for R.N. Barracks, to the *Carlisle*; J. E. Johnston to the *Pembroke*, on commissioning for trials; E. B. Kenny to the *H.M. Dockyard*, Gibraltar, and a H. W. Nicholls to the *Victory* for R.N. Barracks, Portsmouth.

Surgeon Lieutenant Commanders W. F. Beattie to the *Excellent*; J. O. Brown to the *Triad*; C. H. M. Gimlette, J. A. Watson, L. S. Goss, A. W. North, J. J. Carroll, F. H. Vey, and G. Aubrey to the *President*, additional for five months' course at R.N. College, Greenwich.

Surgeon Lieutenant R. G. Anthony to the *Virid*, additional for R.M. Infirmary, Plymouth.

Messrs. W. A. Hopkins and H. A. M. Whitby have entered as Surgeon Lieutenants and appointed to the *Victory*, additional for course at Royal Naval Hospital, Haslar; Messrs. G. Keating and R. B. McVicker have entered as Surgeon Lieutenants and appointed R.N. Hospital, Haslar, for course.

### ROYAL ARMY MEDICAL CORPS.

Major and Brevet Lieutenant-Colonel M. G. Winder, D.S.O., to be Lieutenant-Colonel, vice Lieutenant W. M. B. Sparkes, D.S.O., to retire pay.

Captain (now Major) A. J. Digram, O.B.E., to be acting Lieutenant-Colonel from October 1st, 1919, to May 16th, 1921. (Substituted for notification in the *London Gazette* of April 20th, 1921.)

Captain T. F. Kennedy, O.B.E., relinquishes the temporary rank of Major on ceasing to be employed as a Deputy Assistant Director of Hygiene.

Captain W. H. Ferguson, M.C., relinquishes the temporary rank of Major on ceasing to be employed as a Deputy Assistant Director of Pathology.

Captains J. W. Malcolm, M.C., and F. R. Escribá are granted the local rank of Major for service with the Iraq levies.

The appointment to Captain of J. B. Finch is antedated to March 15th, 1918, with precedence next below A. C. Jebb, but not to carry pay or allowances for the period of antedate.

Captain H. G. Hobson, O.B.E., M.C., is restored to the establishment.

Lieutenant (on probation) F. H. King resigns his commission.

### ROYAL AIR FORCE MEDICAL SERVICE.

Wing Commander H. E. Whittingham to R.A.F. Pathological Laboratory, Halton, for duty as Deputy Director.

Squadron Leader P. T. ... quarters, Egypt.

Flight Lieutenant A. J. ...

Flying Officers R. S. MacLachy to R.A.F. Trans-Jordan Headquarters, Palestine; W. B. ...

... F. W. G. Smith, R. W. ...

... F. W. G. Smith, R. W. ...

... F. W. G. Smith, R. W. ...

### TERRITORIAL ARMY.

#### ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel H. G. G. Mackenzie, D.S.O., having attained the age limit for retention, relinquishes his commission and retains the rank of

M.S.(ret.) to be Major.

O.B.E., M.C., is confirmed in his rank.

### TERRITORIAL ARMY RESERVE OF OFFICERS.

#### ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel C. A. Lees, C.B.E., having reached the age limit, is retired, and retains his rank with permission to wear the prescribed uniform.

Captain P. J. Watkin, M.C., from Active List, to be Captain.

### COLONIAL MEDICAL SERVICES.

Dr. C. B. D. Reid, Medical Officer, transferred from Dar-es-Salaam to Mwanza, Tanganyika; Dr. H. R. Neilson appointed Sanitation Officer and Medical Officer of Health, Kampala, Uganda; Dr. F. R. Freeman, M.C., appointed District M.O. and M.O.H., Mbale, Uganda; Dr. J. E. Hailstone to be Senior M.O., Arua, Uganda; Dr. E. A. C. Langton appointed District M.O., Mbarara, Uganda; Dr. J. C. Caldwell appointed M.O. Jinja, Uganda.

## VACANCIES.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.11.—(1) Resident Medical Officer. (2) House-Surgeon. Salary at the rate of £200 and £120 per annum respectively.

BRIGHTON: ROYAL SUSSEX COUNTY HOSPITAL.—House-Physician (male). Salary £150 per annum.

CARDIFF CITY COUNCIL.—Assistant Medical Officer. Salary £600 per annum.

DERHAM COUNTY MENTAL HOSPITAL, Winterborne, Dorset.—Assistant Medical Officer. Salary £200 per annum, with £100 bonus at present.

EDINBURGH: THE HOSPITAL MATERNITY HOSPITAL.—Resident Medical Officer (female). Remuneration at the rate of £50 per annum.

EDINBURGH HOSPITAL FOR WOMEN AND CHILDREN.—(1) Senior House-Surgeon. (2) Junior House-Surgeon. Females. Salary at the rate of £60 and £40 per annum respectively.

EDINBURGH ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN.—Four Honorary Resident Medical Officers.

HASTINGS: ROYAL EAST SUSSEX HOSPITAL.—Honorary Radiologist.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maidstone, Kent.—Medical Registrar. Honorarium £100.

HOSPITAL FOR TROPICAL DISEASES, Endsleigh Gardens, N.W.—Medical Superintendent. Salary £250 per annum.

KENT COUNTY OPHTHALMIC HOSPITAL, Maidstone.—House-Surgeon. Salary £300 per annum.

LANARK COUNTY.—Medical Officer of Health. Salary £1,300 per annum.

LONDON HOSPITAL, E.1.—Obstetric and Gynaecological Registrar and Tutor. Salary £400 per annum.

LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.1.—Anaesthetist. Small honorarium.

MANCHESTER: ANCOATS HOSPITAL.—Two House-Surgeons. Salary at the rate of £100 per annum for first six months, rising to £150 per annum for second six months.

MARGATE: ROYAL SEA BATHING HOSPITAL FOR SURGICAL TUBERCULOSIS.—House-Surgeons. Salary at the rate of £200 per annum.

MINISTAR OF PENSIONS.—Junior Resident Medical Officer at the Highbury Group of Hospitals, Birmingham. Salary £300 per annum.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.—Assistant Casualty House-Surgeon. Salary at the rate of £100 per annum.

ROCHDALE INFIRMARY.—Radiologist.

ROYAL FREE HOSPITAL, Gray's Inn Road, W.C.1.—Casualty Officer. Salary £100 per annum.

RYDE: ROYAL ISLE OF WIGHT COUNTY HOSPITAL.—Resident House-Surgeon (unmarried). Salary £180 per annum.

ST. MARK'S HOSPITAL FOR CANCER, FISTULA, AND OTHER DISEASES OF THE RECTUM, City Road, E.C.1.—House-Surgeon (male). Salary £200 per annum.

ST. PANCRAS BOROUGH.—Assistant Medical Officer (male) in the Public Health Department. Salary £600 per annum, rising to £700.

SALISBURY: GENERAL INFIRMARY.—House-Surgeon (male). Salary £150 per annum.

SARAJEVO FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W.1.—House-Surgeon. Salary at the rate of £100 per annum.

SEAFORD HOSPITAL SOCIETY.—Physician at the Dreadnought Hospital, Greenwich.

SOMERSET COUNTY COUNCIL.—Assistant Tuberculosis Officer. Salary £600 per annum, rising to £650.

STANLIX DISTRICT MENTAL HOSPITAL, Larbert.—Second Assistant Medical Officer (male). Salary £275 per annum.

STOCK-ON-TRENT: NORTH STYFORDSHIRE INFIRMARY.—House-Surgeon. Salary £150 per annum.

WEST END HOSPITAL FOR NERVOUS DISEASES.—(1) Assistant Physician. (2) Physician for Skin Department. (3) House-Physician (male) for In-patients; salary at the rate of £150 per annum. (4) Clinical Assistant in the Speech Department.

WEST LONDON HOSPITAL, Hammersmith Road, W.6.—Honorary Surgical Registrar. Honorarium £100 per annum.

WILTS COUNTY MENTAL HOSPITAL, Devizes.—Assistant Medical Officer (male). Salary £350 per annum.

WORCESTER GENERAL INFIRMARY.—Senior Resident Medical Officer. Salary £180 per annum.

CERTIFYING FACTORY SURGEONS.—The Chief Inspector of Factories announces the following vacant appointments: Ossett (Yorks, West Riding), Bruton (Somerset).

MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT, 1906, FOR DUNDEE DISTRICT.—Applications to the Private Secretary, Scottish Office, by February 9th.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

### REGULAR ARMY RESERVE OF OFFICERS.

#### LIFE GUARDS.

Surgeon Lieut.-Colonel J. H. Power, having attained the age limit of inability to recall, ceases to belong to the Reserve of Officers.

### SUPPLEMENTARY RESERVE OF OFFICERS.

#### ROYAL ARMY MEDICAL CORPS.

Captain Frederick W. Oldershaw, late Serv. Bns., Lincoln Regiment, to be Lieutenant, December 6th, 1924. (Substituted for notification in the *London Gazette*, December 5th, 1924.)

#### INDIAN MEDICAL SERVICE.

The services of Colonel R. A. Needham, C.I.E., D.S.O., Deputy Director-General, are placed at the disposal of the Railway Department (Railway Board) for a period of one year, from January 1st, and he is placed on special duty.

Lieut.-Colonel J. K. S. Fleming, O.B.E., is appointed Deputy Director-General, Indian Medical Service, from January 1st.

The services of Lieut.-Colonel T. C. McCombie Young are placed at the disposal of His Excellency the Commander-in-Chief (November 20th, 1924).

The services of Major T. D. Morrison are placed permanently at the disposal of the Government of Assam (November 20th, 1924).

The services of Major S. Gordon, M.C., are placed at the disposal of His Excellency the Commander-in-Chief, with effect from the date on which he reports himself for duty to the military authorities.

Major G. M. Millar, O.B.E., is appointed substantively to be an Agency Surgeon under the Government of India in the Foreign and Political Department, with effect from October 3rd, 1924.

Captain (Acting Major) W. E. Brerley relinquished his acting rank on January 31st, 1920, on substantive promotion to the rank of Major (February 1st, 1920).

## APPOINTMENTS.

- CORRY, J., L.R.C.P.Lond., M.R.C.S.Eng., Medical Officer, Paddington Casual Wards, Metropolitan Asylums Board.
- LEWELLYN-JONES, J. G. M.B., Ch.B.Liverp., Workhouse Medical Officer and Public Vaccinator of the Hawarden Union, and Medical Officer of Health and Medical Officer, Isolation Hospital, Hawarden Rural District Council.

### National Insurance.

#### RANGE OF SERVICE: EXTRACTION OF TEETH.

*Decision of a Court of Referees appointed in Scotland.*

For some time the question whether teeth extraction comes within the terms of contract of insurance practitioners has given rise to a good deal of controversy in Scotland, chiefly owing to the activities of the Scottish Rural Workers' Approved Society, which issued a circular to its members in these terms:

"... For simple extractions, where no anaesthetic is necessary, you should consult your panel doctor, who is required under his terms of service to provide such treatment free, as part of your medical benefit."

The Insurance Acts Subcommittee (Scotland) brought this circular to the notice of the Scottish Board of Health, who replied that it had communicated with the Rural Workers' Approved Society, pointing out the machinery provided under the regulations for deciding such questions. The question has now been finally decided by a Court of Referees on a case raised by the Rural Workers' Approved Society with the Roxburgh County Insurance Committee.

The inquiry was held on January 5th. The case for the Local Medical Committee was conducted by the clerk, Mr. James Barrie, and the Committee was advised throughout by the Scottish Medical Secretary of the British Medical Association, Dr. J. R. Drever, who gave evidence at the inquiry, as did also a number of local practitioners.

Appended is the finding of the court.

Having heard the evidence adduced for the Scottish Rural Workers' Approved Society, the Roxburgh County Insurance Committee, the Local Medical Committee, and for Dr. J. M. Lander, and considered the same, we find that there is no custom or practice of the medical profession peculiar to the County of Roxburgh which is relevant to the question which we are asked to determine, and we determine that the extraction of teeth does not come within the scope of an insurance practitioner's obligations under his terms of service with the Insurance Committee.

JAMES A. FLEMING.  
R. C. BUIST, M.D.  
J. E. MOORHOUSE, M.D.

Edinburgh, January 5th, 1925.

#### Note.

The question we are asked to determine is whether the extraction of teeth falls within the scope of the services which medical practitioners who have entered into an agreement with an Insurance Committee have contracted to give.

Section 8 (1) of the Terms of Service for Practitioners, which by Section 3 of the Regulations must be incorporated in any such agreement, provides as follows: "The treatment which a practitioner is required to give to his patient comprises such treatment as is of a kind which can consistently with the best interests of the patient be properly undertaken by a general practitioner of ordinary professional competence and skill."

By Section 2 (1) of the National Health Insurance (Medical Benefits) Consolidated Regulations (Scotland), 1923, which are incorporated in the said Terms of Service by Section 15 thereof, it is provided that "treatment" means medical attendance and treatment, including the issue of medical certificates. Unless, therefore, the extraction of teeth can be held to be medical treat-

ment it is clear that the practitioner is not bound to undertake such an operation.

The National Insurance Act, 1911, grants various benefits to insured persons which are detailed in Section 8 as (a) medical, (b) sanatorium, (c) sickness, (d) disablement, and (e) maternity benefits, and also (f) to certain insured persons the "further benefits" mentioned in Part II of the Schedule IV to that Act. These "further benefits" are in the Act called "additional benefits."

The first of these "further" or "additional" benefits mentioned in that schedule is thus described: "(1) Medical treatment and attendance for any persons dependent upon the labour of a member." The second is thus described: "The payment of the whole or any part of the cost of dental treatment."

Two points are clear from these provisions: first, that dental treatment is for the purposes of the Act something further than or additional to medical treatment, and is not included in that expression; and, second, that dental treatment is a treatment for which additional payment is to be made, even by the member.

It was urged in argument that any service rendered by a practitioner to his patient is a service within his contract unless he can show that it is beyond his competence and that the fact that he did render the service shows that it is within his competence.

That argument ignores entirely the conclusion we have arrived at upon a consideration of the provisions above referred to. It also, even upon the assumption that dental treatment can be considered as included in medical treatment, ignores entirely the standard of competence and skill which is stipulated for in the contract. That standard is the competence and skill possessed by the general body of practitioners and is not the standard of exceptional competence and skill possessed by an individual practitioner. We have no hesitation in rejecting the argument.

There are no special customs or practices in the area in question which throw light on the subject. Out of twenty-one practitioners only three do any dental work, and they all charge for the treatment and for any local anaesthetic supplied.

We desire to express our appreciation of the manner in which each party presented their case. We have also to thank Mr. Gerrard for the excellent manner in which he performed the duties of clerk to the inquiry.

After the note so far had been drafted and submitted to the referees for their approval, Mr. Fleming received the letter enclosed herewith from Mr. Wood, the secretary of the Scottish Rural Workers' Approved Society. In a telephonic conversation with Mr. Wood he stated that his objection is that we were asked to act under the reference to the Board by the Committee was of general question of 1921. He also stated that the referer of December 8th, 1923, but of the general question.

It is, of course, for the Board to say whether they will take action on the lines suggested by Mr. Wood, but we may say that after careful consideration of the Regulations of 1924 and the modifications which they have made on the Regulations of 1923, we are satisfied that there is nothing in them which would allow us to alter the conclusion we have arrived at on the Regulations of 1923, namely, that the treatment prescribed in Section 8 of each set of Regulations does not include dental treatment.

In Section 8 (1) of the Regulations of 1924 the standard of skill for medical treatment is described as of a kind which general practitioners as a class can reasonably be expected to possess, and in Section 8 (4) it is provided that in determining that question "regard is to be had to the question whether services of the kind are or are not usually undertaken by general practitioners practising in the area in which the question arose."

These passages seem to us to confirm the conclusion at which we had arrived, that even on the assumption, which we think is not well founded, that medical treatment includes dental treatment, the standard of skill stipulated for is not the standard of skill possessed by an individual practitioner.

R. C. B.  
J. E. M.

## THE ROYAL COMMISSION.

The fifteenth meeting of the Royal Commission on National Health Insurance was held at the Home Office on January 29th. Sir Andrew Duncan took the chair during the earlier part of the sitting, and Lord Lawrence of Kingsgate later.

Evidence was first received from Mr. J. P. Lewis, C.A., secretary of the Hearts of Oak Benefit Society, on certain points of policy relating to investment of society funds. The main part of the sitting was devoted to the examination of Mr. Alban Gordon, who submitted far-reaching proposals for the reconstruction of the approved society system on a territorial basis and the transfer of medical and allied benefits to a unified local health service embracing all aspects of medical work.

Proof copies of the oral evidence and the relative statements submitted at the meeting of January 15th are now on sale and may be obtained, on remittance of cost (2s. 3d.) and postage, from H.M. Stationery Office, Adastral House, Kingsway, London, W.C.2.

## THE MEETING AT EDINBURGH.

## Correction.

In the report of the meeting held in Edinburgh to discuss the Memorandum of Evidence to the Royal Commission on National Health Insurance (SUPPLEMENT, January 31st, p. 52) the word "not" was inadvertently omitted from the following sentence (line 11 from foot of column): "The meeting was in favour of the inclusion in the national health insurance scheme of the class of persons at present attended under the Poor Law." This should read: The meeting was not in favour, etc.

## Association Notices.

## BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A clinical and pathological meeting of the Nuneaton and Tamworth Division will be held at Atherton on Wednesday, February 25th.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—A meeting of the Hyde Division will be held at the Dukinfield Town Hall to-day (Friday, February 6th), when Dr. Alfred Cox, the Medical Secretary, will address the meeting. Members are requested to bring with them any non-member of the Association residing in the district.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, February 10th, at 9.30 p.m., when Dr. Edwin Smith, coroner for North-East London, will read a paper on some legal relationships of the practitioner.

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—At the meeting of the Lewisham Division to be held at the Parish Room, St. Laurence Vicarage, Catford, S.E.6, on Tuesday, February 17th, at 8.45 p.m., a paper will be read by Mr. Frank Cook, F.R.C.S.

**METROPOLITAN COUNTIES BRANCH: N.—An**  
address will be given to the  
Palace Mansions Hotel (Merrick  
De Vero Hotel, at 8.45 p.m.,  
R. H. Cole, physician in charge  
Hospital, entitled "The present  
treatment of mental disorders."

**METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.**—A meeting of the South Middlesex Division will be held at the St. John's Hospital, Twickenham, on Wednesday, February 25th, at 8.15 p.m., for general business. At 8.30 p.m. Dr. H. C. Corry Mann, O.B.E., will read a paper entitled "Some remarks on dietary during the school age of life."

**METROPOLITAN COUNTIES BRANCH: WEST MIDDLESEX DIVISION.**—A meeting of the West Middlesex Division will be held on Thursday, February 12th, at 8.30 p.m., at the King Edward Memorial Hospital, Mattock Lane, Ealing, when Dr. J. Bell will give an address on some hæmorrhages associated with pregnancy. A discussion will follow.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A dinner will be held at the Comedy Restaurant, Pantons Street, Haymarket, S.W.1, on Sunday, February 15th, at 7 p.m. Tickets can be obtained from Dr. W. Lock, 45, Church Road, N.W.10.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—A clinical and pathological meeting of the Chesterfield Division will be held at the Maternity Hospital, Chesterfield, on Friday, February 13th, at 8.30 p.m., when there will be a demonstration of cases.

**SOUTHERN BRANCH.**—A meeting of the Southern Branch will be held at the South Western Hotel, Southampton, on Friday, February 20th, at 2.45 p.m. Agenda: Correspondence; financial statement; a discussion on the need for public education on what ought to be known about cancer will be opened by the Honorary Secretary, who will move a resolution; to fix date of annual meeting of the Branch at Jersey; to make a collection for Epsom College.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—At the meeting of the Swansea Division to be held at the General Hospital, Swansea, on Thursday, February 12th at 8.15 p.m., a paper will be read by Dr. Daniel E. Evans.

**SOUTH-WESTERN BRANCH: EXETER DIVISION.**—The next meeting of the Exeter Division will be held in the Library of the Royal Devon and Exeter Hospital to-day (Friday, February 6th), at 3.30 p.m., when a lecture will be delivered by Mr. Norman Lock on intestinal obstruction. Tea at 4.30.

**STURARY BRANCH: CROYDON DIVISION.**—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, February 24th, at 8.30 p.m., when Dr. J. A. Ryle will give an address on recent observations on referred pain.

## Meetings of Branches and Divisions.

## CEYLON BRANCH.

The annual general meeting of the Ceylon Branch was held in the Colonial Medical Library on December 17th, when Dr. A. Nett, president, was in the chair.

The following resolution was carried unanimously:

"That this Association begs to submit to Government that General Order No. 224, to the effect that in case of ill health officers in Government employ to tender certificates of ill health from Government medical officers only, is at the present time unjustified and unnecessary; that there are sufficient number of duly qualified medical men in private practice to give such certificates; and that this Order should be so amended as to permit the acceptance by Government Departments of medical certificates issued by qualified medical men."

The report of the Branch Council for the year 1924 was read, and the audited statement of accounts submitted and approved. The following officers were elected for 1925:

President, Dr. P. J. Chiswell. President-Elect for 1926, Dr. H. M. Ferries. Vice-Presidents, Drs. S. T. Gunasekara and C. Brito Babapulle. Honorary Secretary and Treasurer, Dr. Lionel de Silva.

A programme of dates of meetings of the Branch to be held in the Colonial Medical Library during the year was arranged.

## METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.

A MEETING of the Lewisham Division was held on January 20th, at the Parish Room, St. Laurence Vicarage, Catford, when Dr. F. A. Beattie occupied the chair.

Mr. ARTHUR RYLAND delivered an address entitled "Danger signals in the neuro mastoid." He showed a series of lantern slides illustrating the development and structure of the temporal bone. The deciding factor causing complications, he said, was the anatomical structure of the bone, not the virulence of the organism or the resisting power of the patient. The function of the mastoid cells was unknown. The chief variations of the mastoid cells were (1) cellular; (2) acellular; (3) diploic; (4) with a dense outer cortex; (5) infantile; (6) supercellular type. The focal cells were the original group of mastoid cells, and the diploic the original spongy bone cells. The danger signs were first, and most important, bulging of the drum, which ought to be freely incised under a general anaesthetic; second, resistance of local pain, with headache and fever. The acute mastoid abscess was shown by swelling, oedema, and turning of the ear forward. If a rigor occurred the mastoid should be opened. When there was facial paralysis, vertigo, spontaneous nystagmus, and cervical stiffness, the brain of the trouble was being borne by the labyrinth.

Drs. CHARLEY and ORR joined in the discussion, and a vote of thanks to the lecturer was accorded on the proposal of the CHAIRMAN.

## YORKSHIRE BRANCH: HARROGATE DIVISION.

A MEETING of the Harrogate Division was held in the Imperial Café on January 22nd, when Dr. NIMMO WATSON was in the chair.

A paper on orthopaedics and the nervous system was read by Mr. S. W. Daw (Leeds), who, after stating the general orthopaedic principles underlying lesions of the upper and lower neurons, referred to special lesions. In torticollis he condemned passive movements, but advised active movements (with or without resistance) of the muscles that were not contracted. In anterior poliomyelitis affecting the lower limbs early support of the foot with a rectangular splint was necessary. Mr. Daw outlined the surgical treatment where deformities had occurred. Early treatment with Fairbank's splint was advised for Erb's birth palsy. The symptoms associated with cervical ribs, spinal tumour, and spinal caries were given. The treatment by surgical measures of certain cases of paraplegia and hemiplegia, also of Little's disease, was considered. Mr. Daw replied fully to many questions which were raised in the subsequent discussion.

On the motion of Dr. GARRAD, seconded by Dr. HOLMES, a hearty vote of thanks was unanimously accorded to Mr. Daw.

## Correspondence.

## Royal Commission on National Health Insurance.

SIR,—May I draw attention to the great injustice to whole-time medical officers which is proposed in the draft Memorandum of Evidence? Paragraph 27 states, "certain existing clinics or treatment centres . . . would no longer be required." Presumably the whole-time medical officers who run these clinics "would no longer be required" also. This presumption is confirmed by paragraph 28, which states, "for a limited

period of time it would still be necessary to continue the appointment of whole-time officers dealing with tuberculosis and with venereal diseases." Evidently it is the intention eventually to abolish the appointments altogether.

Why should the Council of the British Medical Association take up such a hostile attitude to whole-time medical officers? Last year at the Annual Meeting at Bradford they passed a resolution prohibiting them from taking fees for consultations, and now they wish to deprive them even of their appointments and salaries.

Surely this is both unfair and inconsistent. It is unfair because we whole-time medical officers belong to the same profession as the Council and are all, or nearly all, members of the British Medical Association, and are entitled to as much consideration as any other members, and to as much freedom of action in our choice as to what branch of the profession we wish to follow. It is inconsistent because the British Medical Association very recently agreed to co-operate with the Society of Medical Officers of Health in deciding on and endeavouring to obtain a scale of salaries which would improve the conditions of service of the whole-time medical officers. And now within a few months the British Medical Association is advising that the salaries shall cease to exist. It is also inconsistent because our whole-time appointments have all been advertised in the *BRITISH MEDICAL JOURNAL*, and thus the *JOURNAL* invites us to apply for posts which are approved in the advertisement pages and condemned in the *SUPPLEMENT*.—I am, etc.,

LEONARD CROSSLEY, M.D.,  
County Tuberculosis Officer for Wilts  
since January 1st, 1913.

Winsley, Wilts, Jan. 27th.

#### *The Evidence to be placed before the Royal Commission on National Health Insurance.*

Sir,—I wish to protest as strongly as I can against the way the vote of the profession on the questions in Document D. 12 (*SUPPLEMENT*, January 3rd, p. 9) was taken. There should in all fairness have been a postal vote on a matter of such great importance. The voting by show of hands at large central meetings disenfranchised the remote, rural, and single-handed men. If the object was to dragoon and stampede the profession and to ensure that the views and wishes of the official few should prevail it was successful.—I am, etc.,

Dukinfield, Jan. 25th.

JAMES BRIERLEY, M.D.

•• We have referred this letter to the Medical Secretary, who writes:

The opinion of the Association whenever expressed has always been against postal voting on matters of this kind as being less satisfactory than voting after discussion. Every effort has been made by urging that meetings should be multiplied (even at the risk of overlapping) to get general opinion. The suggestion that any "official few" are wanting to dragoon the rest is absurd, as must be evident to anybody who realizes how extensively the Council has cast its net in the drafting of the document as well as in the methods adopted to get it discussed.

### Naval and Military Appointments.

#### ROYAL NAVAL MEDICAL SERVICE.

### British Medical Association.

#### CURRENT NOTES.

##### Proprietary Medicine Legislation.

THERE are welcome signs that the long and strenuous labours of the Association in connexion with the advertisement and sale of proprietary medicines may before long receive their reward. It is known that the Government of 1920 introduced a bill into the House of Lords which, if passed, would have gone far to remedy the abuses connected with this business. But the bill was withdrawn at the end of its career in the House of Lords for the purpose of securing agreement on one or two points which were the subject of controversy and might possibly have wrecked the bill. It is believed that the present Government intends to proceed with legislation at a convenient time, but when that time will arrive depends a good deal on how far any bill introduced may be regarded as an agreed measure. The persons chiefly concerned in coming to an agreement are the makers of these remedies, the pharmaceutical chemists and others who sell them, the medical profession, and the Government as representing the interests of the public. The recent very significant vote at the Publicity Club of London (SUPPLEMENT to the BRITISH MEDICAL JOURNAL, November 22nd, 1924, p. 189) shows that the responsible persons in connexion with the proprietary medicine trade, as well as those concerned in the advertisement of these wares, are beginning to realize that legislation is inevitable, and that it would be a wise move and an evidence of foresight to try to help forward legislation on lines which, while preserving legitimate interests, would abolish the grave abuses with which this trade is surrounded. The Pharmaceutical Society has now asked the British Medical Association to send representatives to meet representatives of the society to discuss the possibility of pressing for legislation, and no doubt this consultation will be arranged very shortly. It is the intention of the Association, with the help of the medical members of Parliament, to press the Government to take early action, and the prospects of the Government acceding to this request look more than usually promising in view of the circumstances mentioned above.

##### The Sir Charles Hastings Clinical Prize for General Practitioners.

The Council of the British Medical Association has decided to establish experimentally an annual prize—"The Sir Charles Hastings Clinical Prize"—of fifty guineas for an essay or lecture for the purpose of stimulating systematic observation, research, and record in general practice. The Council believes that systematic observation by general practitioners, along selected lines of clinical study, may result in the production of practical contributions of great

value by those who are in a favourable position for following disease through its various stages.

The first prize will be awarded in 1926, and the conditions governing its award, as adopted by the Council on April 16th, 1924, are as follows:

##### Regulations.

1. This prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice; it includes a money award of the value of fifty guineas.
2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.
3. The work submitted must include personal observations and experience of the candidate collected in general practice, and a high order of excellence will be expected. If no essay entered is of sufficient merit no award will be made.
4. Essays, or whatever form the candidate desires his (or her) work to take, must be sent to the Medical Secretary, British Medical Association, 429, Strand, W.C.2, not later than December 31st, 1925, and the prize will be awarded at the Annual General Meeting of the Association. The first award will be made in 1926.
5. If any question arises in reference to the eligibility of the candidate or the admissibility of his essay, the decision of the Council on any such point shall be final.
6. Each essay must be distinguished by a motto, and must be accompanied by an envelope marked with the same motto and including the candidate's name and address.
7. The candidate who gains the award shall, if the Council so desires, publish his paper in the BRITISH MEDICAL JOURNAL or deliver a lecture on the subject thereof at a meeting of the Association.
8. Inquiries relative to the prize should be addressed to the Medical Secretary, 429, Strand, London, W.C.2.

### Association Notices.

#### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A clinical and pathological meeting of the Nuneaton and Tamworth Division will be held at Atherstone on Wednesday, February 25th.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, March 10th, at 9.30 p.m., when Sir H. E. Bruce-Porter will read a paper on medical practice and its pitfalls.

**METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.**—An address will be given to the Kensington Division at Kensington Palace Mansions Hotel (Merrick Room), De Vere Gardens, opposite De Vere Hotel, at 8.45 p.m., to-day (Friday, February 13th), by Dr. R. H. Cole, physician in charge of mental diseases at St. Mary's Hospital, entitled "The present legal disabilities in the early treatment of mental disorders."

**METROPOLITAN COUNTIES BRANCH: LEWISHAM DIVISION.**—A meeting of the Lewisham Division will be held on Tuesday, February 17th, at 8.45 p.m., at the Parish Room, St. Laurence Vicarage, Bromley Road, Catford, S.E.6. Dr. F. A. Beattie will preside. Mr. W. H. Trethowan, F.R.C.S. (Guy's Hospital), will give an address on manipulative surgery.

**METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.**—A meeting of the South Middlesex Division will be held at the St. John's Hospital, Twickenham, on Wednesday, February 25th, at 8.15 p.m., for general business. At 8.30 Dr. L. R. Shore will read a paper on hilum tuberculosis, with some observations on artificial pneumothorax.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A dinner will be held at the Comedy Restaurant, Pantou Street, Haymarket, S.W.1, on Sunday, February 15th, at 7 p.m. Tickets can be obtained from Dr. W. Lock, 45, Church Road, N.W.10. A meeting of the Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, February 25th, at 9 p.m. Agenda:—Dr. W. Lock: Report of Conference at Wembley, 1924, on Venereal Diseases.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—At the meeting of the Chesterfield Division, to be held at the Maternity Hospital, Chesterfield, on Friday, March 13th, Dr. A. J. Hall, professor of medicine, University of Sheffield, will give an address on "Diagnostic Bunkers."

**NORTH OF ENGLAND BRANCH: SHEFFIELD DIVISION.**—A meeting of the Division will be held at the Medical Institute, Sheffield, on Wednesday, February 18th, at 8.15 p.m. Dr. Hall will give a short talk on the diagnosis of spinal paralyses, to be followed by a discussion.

Members are cordially invited to attend a supper which will precede the meeting, commencing at 8.15 p.m., at which Dr. Hall will be the guest of the Division. Members intending to be present for supper are asked to notify Dr. Colin Mearns, 22, Bewick Road, Gateshead, before Wednesday, February 18th.

**SOUTHERN BRANCH.**—A meeting of the Southern Branch will be held at the South Western Hotel, Southampton, on Friday, February 20th, at 2.45 p.m. Agenda: Correspondence; financial statement; a discussion on the need for public education on what ought to be known about cancer will be opened by the Honorary Secretary, who will move a resolution; to fix date of annual meeting of the Branch at Jersey; to make a collection for Epsom College.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—A meeting of the Swansea Division will be held at the General Hospital, Swansea, on Thursday, February 26th, at 8.15 p.m., when Mr. Trevor Hunter, barrister-at-law, will read a paper on the law and medicine.

**SURREY BRANCH: CROYDON DIVISION.**—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, February 24th, at 8.30 p.m., when Dr. J. A. Kyle will give an address on recent observations on referred pain.

**SURREY BRANCH: GUILDFORD DIVISION.**—At the meeting of the Guildford Division, to be held at the Royal Surrey County Hospital, Guildford, on Thursday, March 5th, Sir Crisp English, K.C.M.G., will open a discussion on abdominal pain.

**YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.**—At the meeting of the Wakefield, Pontefract, and Castleford Division, to be held at the Bull Restaurant, Wakefield, on Thursday, March 12th, Mr. E. W. Bain, F.R.C.S. (Leeds), will give a lecture on middle-ear suppuration.

## National Insurance.

### THE ROYAL COMMISSION.

The sixteenth meeting of the Royal Commission on National Health Insurance was held at the Home Office on February 5th, Lord Lawrence of Kingsgate in the chair. The main part of the sitting was devoted to the examination of Mr. F. W. Daniels, chairman, and Mr. P. Rockliff, secretary, of the Joint Committee of Approved Societies. The subjects dealt with included the scope and quality of medical benefit, the possibility of limiting cash benefits so as to leave more funds available for treatment benefits, the benefits of married women, the pooling of surpluses. Thereafter Mr. E. E. England, representing the Stock Exchange Clerks Approved Society and the Baltic and Corn Exchange Society, and Commander E. G. Holdway, representing the Lloyds Health Insurance Society, were examined on a variety of matters relative to these societies.

Proof copies of the oral evidence and the relative statements submitted at the meeting of January 22nd may be obtained from H.M. Stationery Office, Adastral House, Kingsway, London, W.C.2, on remittance of cost (2s. 3d.) and postage.

### THE RECORD CARD.

#### SOME DIFFICULTIES IN A RURAL PRACTICE.

The following is the substance of a reply, made by a West Country insurance practitioner to the county medical officer of health, when the latter had stated (1) that the "panel doctor" is paid to keep Record Cards but does not keep them in such a manner as to make them of any statistical value; and (2) that the county M.O.H. ought to have a right of free access to all Record Cards for the purpose of getting statistics for preventive medicine.

For the benefit of the county medical officer of health, who evidently has not realized what these are, I will quote a few

of the difficulties experienced in keeping Record Cards by a panel doctor in a rural district of this county.

#### A Confusion of Names.

First, I have here the Parliamentary Register for one small village in my practice. Although it gives only the names of the males over the age of 21 and the females over 30 years of age, the list contains the names of 63 Halls, 40 Bonds, 32 Giles, 29 Wills, 25 Smiths.

Of the 63 Halls, 4 are Samuel, 4 are Henry, 4 are Frederick, 3 are James, 3 are Frank, 3 are William. And as there are so many Halls they have called some of them the Clarke-Halls; and as there are so many Clarke-Halls there are now the John-Clarke-Halls, the Willie-Clarke-Halls, and the Henry-Clarke-Halls. When I am asked to visit Kathleen the message is: "It is Kathleen Willie-Clarke-Hall, not Kathleen John-Clarke-Hall." Of the 40 Bonds, 5 are Elizabeth, 4 are Eliza, 4 are Mary, 4 are Henry, 4 are George, 4 are William. Of the 32 Giles, 3 are Henry; they live in three adjacent houses, and are all Henry Giles of Badgers' Holl. Of the Smiths, 10 are John Smith, 3 are John Wm. Smith, 3 are John Henry Smith, 3 are James Smith, 2 are James Edward Smith. And so it goes on.

Now this is only one village in my practice; there are Halls by the score when you take in the whole practice, Bonds by the dozen, and so on. Add to this the fact that none of the houses are numbered, and you add to the confusion. Three John Bonds live in one long unnumbered street, and one of them is a postman. I asked him once: "What do you do with a letter addressed simply 'John Bond, Broad Street?'" He said: "Well, I open it and read it myself first, and if there's no money or anything in it for me I leave it at the house of the nearest John Bond. If I am coming this way the one at the bottom of the street gets it next; if I am going out on my round then the other John Bond gets the next chance at it, and hands it on if it isn't meant for him."

#### The Case of Samuel Hall.

Now let us see what happens when one of the seventeen Samuel Halls in the practice starts to cough. I say "Good-morning; er-er, let me see, you are—er-er, your name is—?" "Sam Hall, sir." So I turn cheerfully to the 3,000 Record Cards that my partners and I are supposed to keep, wade through the 153 Halls, pick out sixteen cards with Samuel Hall on the front, and settle down to find this man's card.

"Which approved society do you belong to?" "The National Health, sir." "I know, but I want the name of the society." "Oh, I don't rightly remember that, sir." "Well, who is the secretary; who do you pay your money to each week?" "They stops it out of my pay, sir." "If you were ill who would give you your sickness benefit?" "Sam Smith, sir." "Then you are in the Past-a-Joke Society." "No I baint, sir, that's my club that I pays into; I be in the Penitential Society for the State."

I then look through the Samuel Halls who are "in the Penitential," and find that there are twelve; so now I ask, "Where do you live?" and the answer is "Long Street." Only eight of the twelve live in Long Street, but which of them is the right one?

"What is your number in your approved society—have you got your card with you?" "No, sir. It's the Penitential, sir, that's all I can tell you. I'm Samuel James Hall of Long Street." "Oh! Samuel James Hall?" "Yes, but I don't know if they put the James on my card."

I then search through the Samuel James Halls and find that there are four, two of whom live in Long Street and are "Penitentials," but that is as far as I can get; this man is either one of the two Samuel James Halls, or possibly entered as one of the eight Samuel Halls. I cannot enter up his illness on any of these cards, since each card has a different member's number on it. Again, the cards come to me sometimes with simply "S. Hall," which may be Sidney. Many cards have Mrs. instead of Miss, and vice versa.

Of course, it eventually turns out that when I picked out sixteen cards to find the right one for one of the seventeen Samuel Halls of the practice, I naturally failed, since the card I really needed was still retained by the Insurance Committee, who sent for it two months ago. It is one of their little failings. In passing, I might add that I have here a letter from the county M.O.H., in which he promises to send me an answer in a day or two. When I say that that letter is four months old and that I have not had that answer yet, it is allowed to infer what may happen if the county M.O.H. is allowed to send for our Record Cards.

#### Other Complications.

That leads on to the next difficulty. In a practice where two men are in partnership, and one partner dies during an influenza epidemic, the remaining man, with double work to do, an epidemic on, the trouble of finding a new partner, and, perhaps,

his own household all down with influenza, has to sort out all his late partner's Record Cards and post them off to the Insurance Committee at once.

Add to this that the practice includes portions of three counties, with three Insurance Committees; that the cards must be carefully sorted out and sent to the right Committees; that for statistical purposes it is important that every case of influenza be entered on the correct Record Card, although one has had to send off half one's cards—and some idea is gained of the torture that these same Record Cards are to a would-be conscientious panel doctor. And, if that is not enough, add the fact that the cards are not returned for some weeks and are frequently lost or asked for when they have never been returned.

Another difficulty occurs when a doctor has two surgeries, and his patients, for reasons of their own, visit one surgery one day and the other the next day, and then he has to attend them at their homes a day or two later. Can he carry 3,000 Record Cards around with him? And what if his partner be called in to see some of the sick? Where are the cards to be kept? Can a doctor possibly find time to enter up every card "when the day's work is over," when his day "ends" at two in the morning?

#### *Etiology and Treatment.*

Why do all these difficulties occur? For the very good reason that the responsibility for keeping the Record Cards has been placed on the wrong shoulders. The authorities imagined, perhaps rightly, that the patient, who is after all the proper person to be made responsible for his own card, would be too slovenly to look after it properly, and so they conceived the "brilliant" idea of putting the responsibility on the already overburdened general practitioner. But one cannot do the wrong thing and expect right results, even when dealing with such "patient oxen" as panel doctors. It does not work; it never can work properly.

The only solutions possible are:

1. Make each insured person responsible for carrying his Record Card about with him, in a grease-proof cover; let him produce it to each doctor he goes to, at each place he gets treatment, and then the county M.O.H. can call on the patient and inspect the Record Card whenever the fancy takes him. (The boggy about the patient not seeing his own card is a myth; the man sees what is on his certificate every time he is ill.)

2. Abolish the present cards.

The idea of having a Record Card is in order to have a reliable record. But how can this be possible when (1) the patient often goes to a non-panel doctor for treatment; (2) hospital surgeons are under no obligation to fill in the record; (3) patients drop out of benefit for two years, have an unrecorded illness, and then return to being insured persons; (4) epidemics prevent accurate records; (5) the cards are sent for by the Insurance Committee and are absent when required; (6) the present Record Cards are admittedly so badly designed that it would be hard to find a solitary panel practitioner who has a word to say in favour of them.

#### ABSORBENT WOOL FOR INSURED PERSONS.

A LETTER has been sent by the Ministry of Health to the Retail Pharmacists' Union with reference to the supply of absorbent cotton-wool to insured persons. It has been represented to the Minister that the existing tariff requirements do not secure the supply of a cotton-wool of uniform quality, and he is advised that the difficulties would very largely be removed by the adoption of a standard sample. An arrangement has accordingly been made with the Manchester Testing House, Royal Exchange, Manchester, to retain a standard sample which, in its opinion, meets the requirements laid down in the Drug Tariff. The Testing House will be prepared to give a definite opinion whether samples submitted for testing are in accordance with the standard sample. The Minister has decided that from July 1st next all absorbent cotton-wool supplied to insured persons shall be in accordance with the requirements of the *British Pharmaceutical Codex*, 1923, and the standard sample of the Manchester Testing House.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

**SURGEON LIEUTENANT COMMANDER A. W. COCKING** to the *Broke*.  
**Surgeon Lieutenants** J. S. Harper to the *Gnat*; J. A. E. Tannian to the *Nautis*; R. Burns to the *Montrose*.

### ROYAL NAVAL VOLUNTEER RESERVE.

**Mr. F. M. B. Allen** has entered as Probationary Surgeon Lieutenant and attached to the Ulster Division.

### ROYAL ARMY MEDICAL CORPS.

**Major R. K. White, D.S.O.**, retires on retired pay, and is granted the rank of Lieutenant-Colonel.

### ROYAL AIR FORCE MEDICAL SERVICE.

**Flight Lieutenant G. McC. Jones** is transferred to the Reserve, Class D.2.  
**Flight Lieutenants** E. N. H. Gray and W. E. Barnes to No. 20 Squadron,

**India:** B. F. Haythornthwaite to No. 28 Squadron, India; P. A. Hall, A. C. Mansford, J. R. Woodrow, J. Prendergast, and T. A. Walker to R.A.F. Depot, on transfer to Home Establishment.

**Flying Officers** T. Glynn to Alrcraft Park, India; A. A. Townsend to Aircraft Depot, India; C. G. J. Nicholls and B. Pollard to Research Laboratory and Medical Officers' School of Instruction, Hampstead, for short course, on appointment to short-service commissions; H. C. C. Patterson to Marine Aircraft Experimental Establishment, Felixstowe; F. L. White to R.A.F. Depot.

### TERRITORIAL ARMY.

#### ROYAL ARMY MEDICAL CORPS.

**Majors (prov.) A. P. Hecat and A. J. Brown** are confirmed in their rank.

**Captain T. W. S. Hills** to be Major.  
To be Lieutenants: Second Lieutenant W. A. Ramsay (late R. Scots), with precedence as from June 20th, 1924; C. C. P. Anning; Supernumerary for Service with the O.T.C., Major P. K. Mitchiner to be Lieutenant-Colonel and to command the Medical Unit of the University of London O.T.C.

### TERRITORIAL ARMY RESERVE OF OFFICERS.

#### ROYAL ARMY MEDICAL CORPS.

**Lieutenant Captain (prov.) A. Massey**, from the Active List, to be Lieutenant.

The announcement regarding Captain A. Morris, which appeared in the *London Gazette* of December 31st, 1918, to be cancelled.

## VACANCIES.

**BIRMINGHAM CITY.**—Assistant Tuberculosis Officer and Assistant Medical Officer in a Sanatorium. Salary £450 per annum.

**BIRMINGHAM AND MIDLAND EYE HOSPITAL.**—House-Surgeon. Salary £110 per annum.

**BLACKPOOL.**—VICTORIA HOSPITAL.—Assistant House-Surgeon. Salary £120 per annum.

**BRIGHTON.**—NEW SUSSEX HOSPITAL.—House-Surgeon. Honorarium £50 per annum.

**BRISTOL GENERAL HOSPITAL.**—(1) Two House-Physicians. (2) House-Surgeon. (3) Resident Obstetric Officer. (4) House-Surgeon to Special Departments. (5) Casualty House-Surgeon. Salary for six months at the rate of £99 per annum, and £100 in the event of second appointment being held.

**BRISTOL ROYAL INFIRMARY.**—(1) Obstetric House-Physician. (2) Casualty House-Surgeon. (3) Two House-Physicians. (4) Four House-Surgeons. (5) House-Surgeon to the Ear, Nose, and Throat Department. (6) House-Surgeon to the Gynaecological, Ophthalmic, and Skin Departments. (7) Dental House-Surgeon. Salary for (1) and (2) £100 per annum, for (3), (4), (5), and (6) £80 per annum, and for (7) £115 per annum.

**BURY AND DISTRICT JOINT HOSPITAL BOARD.**—Resident Assistant to the Medical Superintendent. Salary £400 per annum, increasing to £450.

**CARDIFF CITY MENTAL HOSPITAL, Whitechurch.**—Resident Clinical Assistant (male). Honorarium 50 guineas for six months.

**CHICHESTER HOSPITAL FOR WOMEN, S.W.3.**—Registrar (Gynaecological). Honorarium £50 per annum.

**DERBYSHIRE GENERAL HOSPITAL.**—Junior House-Surgeon (male). Salary £153 per annum.

**DORSET COUNTY HOSPITAL, Dorchester.**—House-Surgeon. Salary £120 per annum.

**DORSET MENTAL HOSPITAL, Berrisford.**—Third Assistant Medical Officer (male). Salary £309 per annum, rising to £350.

**HAMPSHIRE: PARISH OF ST. JOHN.**—Senior and Junior Resident Assistant Medical Officer at the New Eden Hospital. Salary £250 and £150 per annum respectively.

**HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.9.**—Medical Registrar. Honorarium £100.

**HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.**—Surgical Registrar. Salary £300 per annum.

**LANCASHIRE COUNTY COUNCIL.**—Two Dental Surgeons. Salary £600 per annum.

**LEEDS UNIVERSITY.**—Lecturer in Bacteriology. Salary £500.

**LINCOLN CITY AND COUNCIL BOROUGH.**—Medical Officer of Health. Salary £900 per annum.

**LONDON JEWISH HOSPITAL, Stepney Green, E.1.**—Out-patient Assistant. Salary £100 per annum.

**MADRAS AND SOUTH MADRAS RAILWAY.**—District Medical Officer. Commencing salary according to age and qualifications, rising to a maximum of Rs.1,550 per mensem.

**MANCHESTER CITY.**—Assistant Tuberculosis Officer. Salary £540 per annum, plus bonus, at present £170 19s. 9d.

**MANCHESTER: MONSIEUR HOSPITAL FOR INFECTIOUS DISEASES.**—(1) First Assistant Medical Officer. (2) Junior Medical Assistant. Salary £600 and £350 per annum respectively.

**MANCHESTER: ST. MARY'S** .....  
Whitworth Street West  
Officer for the Whitworth  
Salaries £200 per annum. .... Officer for the  
sident Surgical  
and Children).

**NEWCASTLE-UPON-TYNE: ROYAL VICTORIA INFIRMARY.**—Honorary Physician in charge of Electrical and Massage Departments.

**NOTTINGHAM GENERAL HOSPITAL.**—Pathologist. £350 per annum and fees for private work.

**QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.2.**—House-Surgeon (male). Salary at the rate of £100 per annum.

**ROTHERHAM COUNTY BOROUGH.**—Medical Officer of Health. Salary £1,000, rising to £1,250.

**ROYAL CHEST HOSPITAL, City Road, E.C.**—(1) Medical Officer (non-resident) in charge of the Tuberculosis Dispensary Department; salary £250 per annum. (2) Physician with charge of out-patients.

**ROYAL NORTHERN HOSPITAL, Holloway, N.**—(1) Resident Medical Officer. (2) Assistant Surgical Officer. Salary £200 and £150 per annum respectively.

**ST. THOMAS'S HOSPITAL, S.E.**—Resident Assistant Surgeon.

**WEST HAM COUNTY BOROUGH.**—Two Assistant School Medical Officers. Salary £600 per annum each.

**WEST LONDON HOSPITAL, Hammer Smith Road, W.6.**—Honorary Surgical Registrar. Honorarium £100 per annum.

**WESTERN OPHTHALMIC HOSPITAL, Marylebone Road, N.W.1.**—(1) Honorary Dental Surgeon. (2) Senior and Junior House-Surgeons. Salary £150 and £100 per annum.

**WOLVERHAMPTON AND STIFFORDSHIRE HOSPITAL.**—House-Surgeon. Salary at the rate of £150 per annum.  
**YORK CITY COUNCIL.**—Medical Officer of Health and School Medical Officer. Salary £1,000 per annum.

**CERTIFYING FACTORY SURGEONS.**—The Chief Inspector of Factories announces the following vacant appointments: Buntingford (Herts), Tenterden (Kent), Misterton (Notts).

*This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.*

### APPOINTMENTS.

**MACDONALD, A. R., M.R.C.S., L.R.C.P.,** House-Surgeon to the Norfolk and Norwich Hospital, Norwich.

**PIDCOCK, B. HENZELL, M.D., B.S. Lond., F.R.C.S. Eng.,** Assistant Surgeon to the Royal Hanley County Hospital.

**SPURD, Norman A., M.A., M.Ch., B.M.Oxon.,** Member Eton College Medical Board.

**WYATT, W., M.B. Ed.,** Assistant Medical Officer, Fountain Menial Hospital, Tooting, S.W.

**CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn Road, W.C.1.**—House-Surgeons: B. McKelvie, M.D., Ch.B. Vict., J. B. Baird, M.B., Ch.B. N.Z.

**WILLESDEN GENERAL HOSPITAL, Harlesden Road, N.W.10.**—Honorary Anaesthetist: H. A. Faulkner, M.R.C.S., L.R.C.P. Member of the Honorary Medical Staff: F. Melville Harvey, M.R.C.S., L.R.C.P.

**CERTIFYING FACTORY SURGEONS.**—T. F. Arnott, M.B., Ch.B. Glas., for the Bovey Tracey District, co. Devon; A. H. B. Kirkman, F.R.C.S. Ed., for the Staplehurst District, co. Kent.

### DIARY OF SOCIETIES AND LECTURES.

#### ROYAL SOCIETY OF MEDICINE.

**Special Discussion:** Mon., 5.30 p.m., Non-specific Disturbances of Health Due to Vitamin Deficiency. Speakers: Dr. Leonard Williams, Colonel R. McCarrison, Dr. W. Cramer, Dr. G. M. Findlay, and others. (The meeting may be adjourned at 7 p.m. and resumed at 8.30 p.m.)  
**Section of Pathology:** Tues., 8.30 p.m., D. Thomson: Researches on *B. pneumosintes*; G. M. Findlay: Acceleration of the Carcinogenic Action of Tar by Radiant Energy; A. N. Goyle: The Virulence and Toxicogenicity for Mice of "Normal" and "Rough" Forms of *B. enteritidis* Gartner.

**Section of History of Medicine:** Wed., 5 p.m., Mr. G. L. Gask: The Medical Staff of Edward III. Mr. W. Reeve Wallace and Dr. N. G. Horner will exhibit a Paduan diploma of 1523, and Dr. Arthur T. Davies a diploma of Montpellier.

**Section of Dermatology:** Thurs., 4 p.m., Cases. 5 p.m., Dr. Aldo Castellani: Observations on some Skin Diseases common in Central America, with microscopic sections, etc.). 8.30 p.m., Dr. N. Macdonald: Dr. R. M. Beath: Dysostosis

**ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.**—Mon., 8 p.m., Mr. C. P. G. Walsley: Ectopic and Imperfect Descent of the Testis. Wed. and Fri., 5 p.m., Dr. G. S. Williamson: Anatomy and Physiology of the Thyroid Apparatus.

**ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos Street, W.1.**—Thurs., 7.45 p.m., Demonstration by Dr. Henry Meloney (Peking): The Pathology of Experimental Leishmaniasis in the Hamster. 8.15 p.m., Professor D. Blacklock: Schistosomiasis and Goitre in Sierra Leone (illustrated by lantern slides).

**CHLSEAS CLINICAL SOCIETY, Club Room, St. George's Hospital.**—Tues., 8.30 p.m., Discussion: Some Diseases Common to the Climatieric (both sexes); to be opened by Sir Thomas Parkinson and Mr. A. Ralph Thompson.

**HAYMAN SOCIETY OF LONDON, St. Mary's Hospital, Paddington, W.**—Thurs., 8.15 p.m., Clinical Meeting.

**MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.**—Mon., 9 p.m., First Lettsomian Lecture by Sir Bernard Spilsbury: Wounds and Other Injuries.

**ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL, West Smithfield, E.C.1.**—Mon., Tues., Wed., and Thurs., 5 p.m., Sir William I. de Courcy Wheeler: The Conservative Treatment of Fractures of the Pelvis and Lower Extremity.

### POST-GRADUATE COURSES AND LECTURES.

**FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.**—Fri., 5.30 p.m., Lecture: Some points in the Diagnosis and Treatment of Tuberculosis and Cancer of the Larynx. **North-Eastern Post-Graduate College (Prince of Wales's Hospital, Tottenham):** Intensive Course in Medicine, Surgery, and the Special Departments, daily except Saturday, 10.30 a.m. to 5.30 p.m. **Paddington Green, Victoria Hospital, and the Children's Clinic:** Combined Course in Diseases of Children. Two sessions daily. **London Lock Hospital, Lectures:** St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.2: Demonstrations daily. Tues. and Thurs. **Special Lectures, London School of Hygiene and Tropical Medicine, Endleigh Gardens, N.W.1:** Tues. and Thurs., 2 p.m., Clinical Demonstration.

**HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.**—Thurs., 4 p.m., Intussusception.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.**—Mon., Tues., Thurs., and Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Afferent Paths and Physiology of Sensation. Tues., Mon., acute Combined Degeneration. Tues., 3.30 p.m., Cerebral Tumours. Wed., 3.30 p.m., The Optic Cerebro-spinal Fluid; 3.30 p.m., Methods of Otitis Media. Operations, Tues. and Fri., 9 a.m.

**QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.**—Thurs., 5 p.m., Clinical Aspects of Abortion.

**SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Gt. Charles Road, Balham, S.W.12.**—Thurs., 4 p.m., Diagnosis of Gastric Disease.

**WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith, W.**—Mon., 12 noon, Applied Anatomy. Tues., 12 noon, Chest Cases. Wed., 12.15 p.m., Medical Pathology. Thurs., 2 p.m., Genito-Urinary Depart-

ment. Fri., 10 a.m., Gynaecological Operations. Sat., 10 a.m., Medical Diseases of Children. Daily 10 a.m. to 5 p.m., Sat., 10 a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.

**GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.**—At Ear, Nose, and Throat Hospital: Wed., 4.15 p.m., Cases.

**LIVERPOOL UNIVERSITY CLINICAL SCHOOL.**—3.30 p.m., daily. Mon., Samaritan Hospital: Significance of Uterine Haemorrhage in Gynaecological Diagnosis. Tues., Maternity Hospital: Caesarean Section. Thurs., St. George's Skin Hospital: Skin Cases.

**MANCHESTER: ANTONIS HOSPITAL.**—Thurs., 4.30 p.m., Diseases of the Oesophagus.

**MANCHESTER: ST. MARK'S HOSPITALS.**—Whitworth Street West Branch: Fri., 4.30 p.m., Ante-Natal Management.

**ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.**—Tues., 4 p.m., Albuminuria in Diseases other than those primarily of the Kidney. (Thurs., February 24th, Renal Insufficiency in Relation to the Risk of Surgical Procedure. Tues., March 3rd, Albuminuria and Pregnancy.)

### British Medical Association.

OFFICES AND LIBRARY, 112, STRAND, LONDON, W.C.2.

#### Reference and Lending Library.

**THE READING ROOM,** in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

**LENDING LIBRARY:** Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 6d. for each volume for postage and packing.

#### CURRENT NOTES.

##### Royal Commission on National Health Insurance.

THE Council of the British Medical Association, at its meeting on Wednesday, February 18th, received a report of the replies of the local meetings of the profession upon the questions submitted with respect to the draft Memorandum of Evidence proposed to be given by the Association before the Royal Commission on National Health Insurance. The Council received also the draft Memorandum of Evidence as revised in accordance therewith by the joint meeting of the Royal Commission Committee and the Insurance Acts Committee. The revised Memorandum as approved by the Council will appear in the SUPPLEMENT to the BRITISH MEDICAL JOURNAL of February 28th, and will thus reach all members of the Association. Further, copies of the SUPPLEMENT in question will be forwarded direct from the Head Office to all non-members of the Association in Great Britain. The Council, as already intimated, will summon a Joint Conference of Representatives of Divisions and of Local Medical and Panel Committees to be held in London on March 12th for the purpose of considering the revised draft Memorandum of Evidence, and it is hoped that, between the issue of the document in the SUPPLEMENT of February 28th and the date of the Conference, Divisions of the Association and Local Medical and Panel Committees will hold meetings for the purpose of instructing their representatives as to their views, in anticipation of the discussion which will take place at the Joint Conference on March 12th. Honorary secretaries of Divisions and Local Medical and Panel Committees should note that the Council will invite to the Conference on March 12th (a) all Representatives of Representative Body Constituencies holding office for 1924-25, and (b) all Panel Conference Representa-

tives appointed by the Local Medical and Panel Committees for the session 1924-25, unless the Medical Secretary is notified that deputies are acting on this occasion.

##### Election of Council.

There are two vacancies upon the Council for the period commencing with the Annual Meeting at Bath next July among the members of Council appointed by the Oversea groups of Branches. As will be seen from the Association Notice in another page, two nominations have been received in respect of the African Group, with the result that voting papers will be issued towards the end of this month to the members of those Branches. It is a pity that no nominations have been received from the Hong-Kong and China and Malaya Group, especially in view of the opening ceremony of the new house of the Association. It now rests with the Council of the Association either to fill the vacancy itself or require nominations from members of the Branches.

##### The Association's Policy for Assistant School Medical Officers.

It is gratifying to see that some progressive education authorities are adopting the policy of the British Medical Association as to the qualifications of their assistant school medical officers. In order to justify the demand for a minimum commencing salary of £600 a year, the Association stipulated that such an officer should have had not less than three years' experience since qualification, and in view of that fact and of the knowledge that comparatively few assistant school medical officers rise to higher rank or much higher salary, such a commencing salary must be regarded as reasonable. The county borough of West Ham, which has distinguished itself by stipulating that "applicants must be members of their professional association," is now advertising for an assistant school medical officer, demanding the three years' experience since qualification, and stating that the D.P.H. will be considered a recommendation.

## Association Notices.

### ELECTION OF MEMBERS OF COUNCIL OF ASSOCIATION BY BRANCHES OUTSIDE THE UNITED KINGDOM.

Two candidates (Dr. J. BARCROFT ANDERSON, East London, South Africa, and Mr. ALFRED R. FUEL, London, England) have been nominated to represent the African Group of Branches upon the Council of the Association for the three years 1925-26. Voting papers will therefore be posted from the Head Office on Monday, March 2nd, 1925, to every member of the Branches in the Group—namely: Border (South Africa), Cape of Good Hope (Eastern), Cape of Good Hope (Western), Egyptian, Gibraltar, Grigoland West, Kenya, Malta, Natal Coastal, Natal Inland, Nyasaland, Orange Free State and Basutoland, Pretoria, Rhodesian, Sierra Leone, Tanganyika Territory, Uganda, Witwatersrand, and Zanzibar. The voting papers must be returned so as to reach the Medical Secretary, British Medical Association, 429, Strand, London, W.C.2, not later than May 16th, 1925.

There were no nominations in respect of the Hong Kong and China and Malaya Branches.

The following are the other Representatives on the Council for the Groups of Branches outside the United Kingdom:

Mr. T. P. DUNHILL, C.M.G. (was elected for the three years 1924-27), South Australian, Tasmanian, Victorian, and Western Australian Branches.

Dr. DAVID EWART, O.B.E. (was elected for the three years 1923-26), New Zealand and Fiji Branches.

Dr. F. J. GOMEZ (was elected for the three years 1923-27), West Indian and Canadian Group of Branches.

Lieut.-Colonel J. W. F. RAIT, I.M.S.(ret.) (was elected for the three years 1923-27), Indian Group of Branches.

Sir JENNER VERRALL, LL.D. (was elected for the three years 1924-26), New South Wales and Queensland Branches.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: NUNEATON AND TAMWORTH DIVISION.**—A clinical and pathological meeting of the Nuneaton and Tamworth Division will be held at Athlerton on Wednesday, February 25th.

**BORDER COUNTIES BRANCH: DUMFRIES AND GALLOWAY DIVISION.**—The next meeting of the Dumfries and Galloway Division will be held in the Royal Infirmary, Dumfries, on Thursday, February 26th, at 3.30 p.m. The business includes consideration of the report of the Scottish Departmental Committee on Puerperal Morbidity and Mortality.

**KENT BRANCH: DARTFORD DIVISION.**—A meeting of the Dartford Division will be held at the New Erith Hospital at 3 o'clock on Friday, February 27th. Mr. H. S. Souttar, C.B.E., F.R.C.S., of the London Hospital, will give an address on modern treatment of fractures, and it is hoped that all practitioners in the Dartford area will be able to attend.

**EDINBURGH BRANCH.**—The winter clinical meeting of the Edinburgh Branch will be held in the Royal Infirmary, Edinburgh, on Friday, February 27th. All members of the profession are cordially invited. Senior medical students desirous of attending will be admitted by card, obtainable from Mr. F. E. Jardine. The museum will be open from 10 a.m. to 6 p.m. Arrangements will be made for holding special clinics during the day. The clinical meeting will be held at 3.30 p.m. Dinner at 6.30 in the Caledonian Station Hotel (morning dress); dinner ticket, price 10s. 6d.

**LANCASHIRE AND CHESHIRE BRANCH: HYDE DIVISION.**—At a meeting of the Hyde Division to be held at the Hyde Town Hall on Thursday, March 12th, at 8.30 p.m., Dr. Ralphs will give his impressions of a short visit to the United States of America.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, March 10th, at 9.30 p.m., when Sir R. E. Bruce-Porter will read a paper on medical practice and its pitfalls.

**METROPOLITAN COUNTIES BRANCH: KENSINGTON DIVISION.**—The Kensington Divisional dance will be held at the Kensington Town Hall on Thursday, May 7th. All money over after expenses have been paid will be handed to the Royal Medical Benevolent Fund and the Royal Medical Benevolent Guild. Further details will appear later, or can be obtained from the Honorary Secretary, 20, Upper Phillimore Place, W.8.

**METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.**—A meeting of the South Middlesex Division will be held at the St. John's Hospital, Twickenham, on Wednesday, February 25th, at 8.15 p.m., for general business. At 9.30 Dr. L. R. Shore will read a paper on hilum tuberculosis, with some observations on artificial pneumothorax.

**METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.**—A meeting of the Division will be held at the Willesden General Hospital, Harlesden Road, on Wednesday, February 25th, at 9 p.m. Agenda:—Dr. W. Lock: Report of Conference at Wembley, 1924, on Venereal Diseases.

**NORTH OF ENGLAND BRANCH: CONSETT DIVISION.**—A social meeting of the Consett Division will be held in the Railway Hotel, Consett, on Wednesday, February 25th, at 8 p.m., when Dr. George Hall, C.M.G., consulting physician, Royal Victoria Infirmary, Newcastle-

upon-Tyne, will be entertained by the Division. After the supper Dr. Hall will address the meeting on the subject of epidemic encephalitis. Supper (tickets 5s. each) will be served at 8 p.m. prompt, and it is hoped that as many members as possible will be present to meet Dr. Hall. To facilitate the arrangements for the supper, members intending to be present should notify the Honorary Secretary (Dr. J. Charles, Hillside House, Stanley, S.O.) not later than Monday, February 23rd.

**SOUTH WALES AND MONMOUTHSHIRE BRANCH: SWANSEA DIVISION.**—A meeting of the Swansea Division will be held at the General Hospital, Swansea, on Thursday, February 26th, at 8.15 p.m., when Mr. Trevor Hunter, barrister-at-law, will read a paper on the law and medicine.

**SOUTHERN BRANCH: WINCHESTER DIVISION.**—A meeting of the Winchester Division will be held at 4, The Square, Winchester, on Thursday, March 19th, at 3.30 p.m., when a British Medical Association Lecture will be given by Professor H. Maclean on the present position of endocrine diseases from a clinical standpoint.

**SURREY BRANCH: CROYDON DIVISION.**—A meeting of the Croydon Division will be held at the Croydon General Hospital on Tuesday, February 24th, at 8.30 p.m., when Dr. J. A. Kyle will give an address on recent observations on referred pain.

**SURREY BRANCH: GUILDFORD DIVISION.**—At the meeting of the Guildford Division, to be held at the Royal Surrey County Hospital, Guildford, on Thursday, March 5th, Sir Crisp English, K.C.M.G., will open a discussion on abdominal pain.

## Meetings of Branches and Divisions.

### EGYPTIAN BRANCH.

The Egyptian Branch of the British Medical Association held a clinical meeting at the School of Medicine, Kasr-el-Aini, Cairo, on January 26th. Sixty-seven members and other medical men were present.

A paper was read by Dr. CAROLINE MAULE on the prevention and control of diphtheria (the Schick test). This paper had originally been read at Bordeaux at the International Health Congress last summer. A very active and interesting discussion was carried on afterwards by SUHAIB PASHA, Under Secretary of State, Public Health, Mr. MADNET, and the medical officers interested in the epidemic work of Egypt. Later on a clinical evening was held, in which many interesting cases illustrating the diseases peculiar to Egypt were shown and discussed.

It is hoped that this will be the first of a very large number of similar successful meetings in the future.

### BORDER COUNTIES BRANCH.

A MEETING of the Border Counties Branch was held at Dumfries and Galloway Royal Infirmary on December 18th, 1924, when Dr. M. Bryson (President) was in the chair.

The meeting unanimously supported the resolution of the Branch council to make an offer to the Council of the Association of a flag for the new hall, bearing the arms of the City of Carlisle, to commemorate the Association's visit there in 1899.

A discussion on fractures, their diagnosis and treatment, was opened by Dr. G. R. LIVINGSTON, followed by Dr. R. COXWELL (who showed many most interesting skiagraphs), Mr. NORMAN MACLAREN, Drs. M. KERR, J. E. BOWSER, J. D. ROBSON, J. CROFT, M. BRYSON, and others.

Tea was provided by the President, and afterwards Dr. LIVINGSTON gave a demonstration of splints and Hey Groves appliances.

### LANCASHIRE AND CHESHIRE BRANCH: WARRINGTON DIVISION.

A most enjoyable evening was spent by the Warrington Division on February 12th, on the occasion of the annual dinner. Dr. ARTHUR ANDERSON was in the chair, and there were twenty-eight others present, among the visitors being Dr. G. C. ANDERSON (Deputy Medical Secretary), Dr. CONRAD STURROCK, Dr. S. E. CRITCHLEY, Dr. JAMES, and Dr. JEANS.

Following the usual toasts, interspersed with musical items, Dr. E. J. FOX proposed that of the British Medical Association. He pointed out the danger of its becoming the organ of the majority, and raised again the question of medical defence. Dr. G. C. ANDERSON responded in an extremely able and satisfying speech, referring in particular to the extensive ramifications of the Association, the activities in India, Malaya, and Canada (where Empire work had been done), to the necessity of the majority prevailing—at the same time illustrating that all medical classes were catered for. He gave the Division to understand that the question of medical defence was being very seriously considered by the appropriate committee of the Association in order that the Council might report to the Representative Body this year as to the advisability of the Association taking up the matter.

### NORTH LANCASHIRE AND SOUTH WESTLORLAND BRANCH.

A CLINICAL meeting of the North Lancashire and South Westmorland Branch was held at Calgarth Hospital, Windermere, by kind permission of Mr. Hough, on January 22nd. There were twenty-nine present, which, taking into account the scattered area of the Branch and the prevalence of influenza, was considered a very excellent attendance. A highly interesting and instructive paper, entitled "The chronic abdomen," was given by Mr. WILSON H. HEY, M.B., F.R.C.S. (Manchester). The discussion that followed showed how much the paper had been appreciated and the novel points noted. Mr. Hey briefly replied. Votes of thanks to Mr. Hey and to Mr. Hough concluded the meeting.

## National Insurance.

## A NATIONAL INSURANCE INQUIRY.

WE have received from the Ministry of Health various documents relating to a committee of inquiry into the professional conduct of a Salford insurance practitioner. The documents include a full report of the inquiry and the formal announcement of the Minister's decision. The case was exceptional in that the respondent practitioner (whom we prefer to write of as Dr. X) pleaded guilty to certain acts which the Court of Inquiry (duly constituted by the Medical Benefit Regulations, 1924) described in its report as "deliberately fraudulent with no justification." Dr. X's application that the inquiry should be held in private was rejected and the case was heard in public. It appeared that Dr. X had, after the charges had been notified to him, sold his practice and had sent in his resignation from the panel, but the resignation was not allowable. Moreover, his counsel decided not to call Dr. X and to withdraw from the inquiry altogether, but this was not permitted to prevent the inquiry proceeding.

To understand properly the charges which were brought against Dr. X by the Salford Local Medical and Panel Committee, it should be noted that the remuneration of the Manchester and Salford panel practitioners is on the system of "payment per attendance," each doctor being provided with a day book in which he has to enter every attendance given to insured persons. At the end of each quarter the Panel Committee, taking into account the amount of money available for distribution to the panel doctors and the total attendances given by all the panel doctors, has to decide what fee can be paid for each attendance, having regard to the various sorts of attendances, such as visits, consultations, operations, etc., and after some allowances for contingencies have been made, each doctor whose claim is passed is paid, on account, in proportion to the number of his actual attendances, any balance remaining being distributed at the end of the year. Thus it is the duty of the Panel Committee carefully to scrutinize the doctors' day sheets and to see that payment is only made for attendances actually rendered, as overpayment to any one doctor would inflict an injustice on all the others. A good deal of reliance has to be put on the honour of the doctors, but there is no reason to believe that this confidence has been abused to any appreciable extent, though the case in question appears to be an example of such abuse.

The charges brought against Dr. X were briefly as follows:

1. That he had entered on his day sheets attendances on an insured person, Mr. A, which he had not rendered. It appeared that when Dr. X was attending a child of Mr. A, the mother of the child offered to pay Dr. X's fee, but he refused to accept the fee, and obtaining the father's medical insurance card, marked the attendance on the day sheets as attendance rendered to Mr. A himself and gave prescriptions on the official form, thus imposing an improper charge on the panel fund and the drug fund.
2. That Dr. X entered on his day sheets four attendances on another insured person, Mr. B, which had never been made, for the purpose of getting payment from the Insurance Committee.
3. That Dr. X entered three attendances on an insured woman which had never been made. This charge was withdrawn as it was impossible to obtain the woman as a witness at the inquiry.
4. Dr. X was charged with signing certificates on the official form, stating that he had examined an insured person on the dates named, though he had not in fact done so. This charge was also withdrawn though it was admitted that Dr. X's assistant had signed the certificates, although neither Dr. X nor the assistant had seen the person on the dates named.
5. This was a charge that Dr. X had issued a prescription without any examination, and this was admitted to be the case.
6. That Dr. X issued a prescription to an insured person though he knew that another panel doctor was attending the person. On this charge Dr. X was acquitted.

As regards charges 1 and 2, Dr. X's counsel admitted on behalf of Dr. X that attendances which had not been made had been entered on the day sheets and payment for them claimed from the Insurance Committee, the only excuse being that Dr. X was at the time working under great difficulties owing to epidemics of measles and influenza. Though these charges were admitted, evidence was given in full detail before the inquiry committee, witnesses being duly sworn and the relevant day sheets and other documentary evidence being produced.

The inquiry committee held that these two charges were proved, and reported to the Minister of Health that Dr. X "deliberately

and fraudulently caused false entries to be made on the day book sheets," and issued a prescription in the name of Mr. A, which was really intended for an uninsured child.

As a result of the inquiry, the Minister of Health has decided to remove Dr. X from the panel list for Manchester and Salford, as he is adjudged guilty of conduct prejudicial to the efficiency of the medical service of the insured; and it is further ordered that the costs of the Panel Committee, to be taxed as between party and party, shall be paid by Dr. X.

The gross irregularities outlined above were fully proved and admitted by Dr. X himself, and as the regulations stand the Panel Committee could not do otherwise than bring the case forward in the prescribed way. Had it not done so the Committee would have forfeited the confidence of the insurance doctors, who look to it for protection against fraudulent demands on the medical benefit pool. The case is of general interest, however, because it shows that the inquiry committees appointed by the Minister of Health are now being called on to give verdicts, where definite fraud is alleged, like a jury in a court of common law, and that the Minister is at liberty to publish as he thinks fit to all insurance committees and to the medical profession, through the medical press, his decision that a panel doctor has been adjudged guilty of fraud by a tribunal so constituted. Apart altogether from the merits—or rather the demerits—of the case in question, it may reasonably be contended that when charges of fraud are to be inquired into the inquiry committee should sit in private, or that the Minister of Health should avail himself of the provision of paragraph 62 of the Medical Benefit Regulations, 1924, which provides that where the alleged facts "are, or may be, the subject of investigation by any other tribunal, he (the Minister) may, if he thinks fit, direct that no further steps shall be taken under this part of the regulations pending the issue of such other investigation."

## THE ROYAL COMMISSION.

THE seventeenth meeting of the Royal Commission on National Health Insurance was held at the Home Office on February 12th, Lord Lawrence of Kingsgate in the chair. Mr. C. H. Waring, representing the Group of Catholic Approved Societies, gave evidence on questions of additional benefits and insurance of married women. Thereafter the examination of Mr. F. W. Daniels, chairman, and Mr. P. Rockliff, secretary, of the Joint Committee of Approved Societies, was continued and concluded. The National Insurance Beneficent Society, represented by Mr. G. W. Canter and Mr. P. Rockliff, was then heard on the question of its administration of treatment benefits.

Proof copies of the oral evidence and the relative statement submitted at the meeting of January 29th may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2, on remittance of cost (2s. 3d.) and postage.

## VACANCIES.

- BATH: ROYAL UNITED HOSPITAL.—Honorary Anaesthetist.  
BIRMINGHAM: GENERAL HOSPITAL.—Medical Registrar and Resident Medical Officer. Salary £355 per annum.  
BIRMINGHAM AND MIDLAND HOSPITAL FOR WOMEN.—House-Surgeon. Salary at the rate of £75 per annum.  
BRIGHTON: NEW SUSSEX HOSPITAL.—House-Surgeon. Honorarium £50 per annum.  
BRISTOL GENERAL HOSPITAL.—(1) Two House-Physicians. (2) House-Surgeon. (3) Resident Obstetric Officer. (4) House-Surgeon to Special Departments. (5) Casualty House-Surgeon. Salary for six months at the rate of £80 per annum, and £100 in the event of second appointment being held.  
BRISTOL ROYAL INFIRMARY.—(1) Obstetric House-Surgeon. (2) Casualty House-Physicians. (3) Four House-Surgeons. (4) Four House-Physicians. (5) Four House-Surgeons. Ear, Nose, and Throat Department. (6) House-Physicians. Ophthalmic, and Skin Departments. Salary for (1) and (2) £100 per annum, for (3) £116 per annum, for (4) £130 per annum, for (5) £140 per annum, for (6) £150 per annum.  
B. HOSPITAL BOARD.—Resident Assistant to the Salary £400 per annum, increasing to £450.  
CAMBRIDGE: ANDENBROOKE'S HOSPITAL.—House-Surgeon (male). Salary at the rate of £150 per annum.  
CROYDON GENERAL HOSPITAL.—Junior House-Surgeon (male). Salary £150 per annum.  
HINSTEAD: PARISH OF ST. JOHN.—Senior and Junior Resident Assistant Medical Officer at the New End Hospital. Salary £250 and £150 per annum respectively.  
HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Surgical Registrar. Salary £300 per annum.  
KING'S LYNN: WEST NORFOLK AND KING'S LYNN HOSPITAL.—Assistant Resident Medical Officer. Salary £100 per annum.  
LAVENSHIRE COUNTY COUNCIL.—Two Dental Surgeons. Salary £600 per annum.  
LITCHFIELD ROYAL INFIRMARY.—Two Surgical Dressers. Honorarium 10s. 6d. per week.

LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.1.—Dermatologist.  
 MANCHESTER: ANCOATS HOSPITAL.—(1) Resident Medical Officer (male).  
 (2) Pathological Registrar. Salary at the rate of £175 and £100 per annum respectively.  
 MANCHESTER: CHRISTIE HOSPITAL.—Cancer Research Worker. Stipend £500 per annum.  
 MANCHESTER CITY.—Assistant Tuberculosis Officer. Salary £540 per annum, plus bonus, at present £170 18s. 9d.  
 MANCHESTER ROYAL INFIRMARY (Central Branch).—(1) Resident Medical Officer. (2) Assistant Medical Officer. (Ladies.) Salary £200 and £100 per annum respectively.  
 NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Assistant Ophthalmic Surgeon.  
 NEWCASTLE-UPON-TYNE: HOSPITAL FOR SICK CHILDREN.—Senior and Junior Resident Medical Officers. Salary at the rate of £120 and £100 per annum respectively.  
 NEWCASTLE-UPON-TYNE: PRINCESS MARY MATERNITY HOSPITAL.—Assistant Resident Medical Officer. Salary at the rate of £40, rising to £80 on appointment as Senior Resident Medical Officer.  
 NEWPORT EDUCATION COMMITTEE.—Assistant School Medical Officer and Medical Inspector of Schools (male). Salary £500 per annum.  
 NOTTINGHAM GENERAL HOSPITAL.—Pathologist. £350 per annum and fees for private work.  
 PORTSMOUTH: ROYAL PORTSMOUTH HOSPITAL.—Senior House-Surgeon (male). Salary at the rate of £200 per annum.  
 QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.—(1) Two Assistant Resident Medical Officers. (2) Senior Resident Medical Officer. Salary for (1) at the rate of £80, and for (2) £100 per annum.  
 ROTHERHAM COUNTY BOROUGH.—Medical Officer of Health. Salary £1,000, rising to £1,250.  
 ROYAL CHEST HOSPITAL, City Road, E.C.—Physician with charge of out-patients.  
 ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury.—(1) Resident Surgical Officer; salary at the rate of £80 per annum for six months, rising to £120 if appointed Resident Medical Officer. (2) Assistant Medical Officer for Out-patients' Department, Garside Street; salary at the rate of £150 per annum for six months, rising to £200 on appointment as Medical Officer.  
 ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W.1.—House-Surgeon. Salary £150 per annum.  
 RUGBY: HOSPITAL OF ST. CROSS.—Senior and Junior Resident Medical Officers (males). Salary at the rate of £150 and £100 per annum respectively.  
 SALFORD ROYAL HOSPITAL.—(1) House-Surgeon. (2) Casualty House-Surgeon. Salary at the rate of £150 per annum each.  
 SALFORD UNION INFIRMARY.—Assistant Resident Medical Officer (male). Salary £275 per annum.  
 SUMNERIAN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W.1.—(1) Surgeon to In-patients. (2) Surgeon to Out-patients.  
 SHEFFIELD: JESSOP HOSPITAL FOR WOMEN.—Honorary General Physician.  
 STOCKTON AND THORNHAY HOSPITAL.—Senior House-Surgeon. Salary £250 per annum.

 WILLESDEN GENERAL HOSPITAL, Harlesden Road, N.W.10.—Honorary Radiologist.  
 WIR HOSPITAL, Grove Road, Balham, S.W.12.—Junior Resident Medical Officer (male). Salary £100 per annum.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

## DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.  
 Section of Odontology: Mon., 8 p.m., Mr. F. N. Doubleday: Some Drugs and Solutions used in Local Anaesthesia. Experimental evidence will be shown at 7.30 p.m.  
 General Meeting of Fellows: Tues., 5.30 p.m., Ballot for Fellowship.  
 Section of Medicine: Tues., 5.30 p.m., Clinical Meeting at Westminster Hospital. Tea, 5 p.m.  
 Section of Pathology: Wed., 5 p.m., Dr. Nathan Raw: Cerebral Cereulosis in Man and Animals.  
 Section of State Medicine: Thurs., 5.30 p.m., Dr. Edinburgh: The Preventive Control of Diphtheria.  
 Section of Urology: Thurs., 8.30 p.m., Dr. Archer and Dr. Robb: Tolerance of the Body for Urea in Health and Disease; to be followed by a discussion in which Drs. H. Maclean, G. A. Harrison, and de Vesselow will take part. Mr. K. M. Walker: A New Diathermy Pouch Operation for Prostatic Obstruction.  
 Section of Study of Disease in Children: Fri., 5 p.m., 4.30 p.m. Cases.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.—Mon., Wed., and Fri., 5 p.m., Dr. G. W. de P. Nicholson: The Nature of Tumour Formation.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Mon., 8.30 p.m., Sir G. Lenthall Cheate, K.C.B.: The Early Stages of Pathological Hyperplasia in the Breast, with Special Reference to Cysts and their Danger.  
 UNIVERSITY OF LONDON.—At 1, Wimpole Street, W.1: Wed., 5 p.m., Lecture by Professor R. Cruchet: The Relation of Paralysis Agitans to the Parkinsonian Syndrome of Epidemic Encephalitis.

## POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND SURGERY.—At 1, Wimpole Street, W.1.—Of Wales's General Hosp. Medicine, Surgery, and all the exception of Saturday, until 5.30 p.m., and will include Demonstrations, Medical and Surgical Clinics, Operations, and opportunity for study in the Special Departments. Lectures at 4.30 p.m. London Lock Hospital, 91, Dean Street, W.1: Comprehensive Course, Clinical Work daily, and Lectures. St. John's Hospital for Diseases of the Skin, Leicester Square, W.C.1.

Demonstrations daily in the various departments. Pathological Demonstrations arranged for. Special Lectures, Tues., 5 p.m., Alpecci; Thurs., 5 p.m., Leukemias, Cutis Mycosis Fungoides. Tickets for this particular course from the Fellowship, London School of Hygiene and Tropical Medicine, Endleigh Gardens, N.W.1: Tues. and Thurs., 2 p.m., Clinical Demonstrations.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Arthritis in Childhood.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Mon., Tues., Thurs., and Fri., 2 p.m., Out-patient Clinics. Tues., 12 noon, Motor System—Pyramidal and Extra-pyramidal; £30 p.m., Myasthenia Gravis. Tues., 3.30 p.m., Cerebral Tumors. Wed., 3.30 p.m., The Optic Nerve. Thurs., 12 noon, Cerebro-spinal Fluid. Thurs., 3.30 p.m., Methods of Testing the Eighth Nerve. Fri., 3.30 p.m., Recurrent Vertigo. Operations: Tues. and Fri., 9 a.m.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.—Thurs., 5 p.m., Albuminuria in Pregnancy.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Onseley Road, Balham, S.W.12.—Wed., 4 p.m., Abdominal Disorders.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammer-smith, W.—Mon., 12 noon, Applied Anatomy. Tues., 12 noon, Chest Cases. Wed., 12.15 p.m., Medical Pathology. Thurs., 11 a.m., Gynaecological Wards. Fri., 2 p.m., Surgical Out-patients. Sat., 10 a.m., Medical Diseases of Children. Daily 10 a.m. to 6 p.m., Sat. 10 a.m. to 1 p.m., In- and Out-patient Operations, Special Departments.

## British Medical Association.

OFFICES AND LIBRARY, 173, STRAND, LONDON, W.C.1.

### Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 6d. for each volume for postage and packing.

### Departments.

SUBSCRIPTIONS AND ADVERTISEMENTS (Financial Secretary and Business Manager. Telegrams: Articulate Westrand, London).  
 MEDICAL SECRETARY (Telegrams: Mediocræ Westrand, London).  
 EDITOR, British Medical Journal (Telegrams: Autology Westrand, London).  
 Telephone number for all departments: Gerrard 2630 (3 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rindall Square, Edinburgh (Telegrams: Associate Edinburgh, Tel. 4561 Central).  
 IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin (Telegrams: Baclinn, Dublin. Tel. 4731 Dublin).

### Diary of the Association.

FEBRUARY.  
 20 Fri. London: Science Committee, 2.30 p.m.

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

### BIRTHS.

MATTHEW.—On February 15th, at Redgarth, Dundee, to the wife of Dr. David Matthew, a son.

MILLER.—At Cardiff, on February 7th, to Dr. Charles Booth Meller and Mrs. Emily Matilda Meller, M.B., Ch.D. (née McCandless), a daughter.

### DEATH.

JONES.—On February 10th, at 39, Hyde Park Gate, London, Evan Jones J.P., V.D., late of Aberdare, Glamorgan, in his 88th year. Interred at St. Fagan's Church, Aberdare, Glam., on February 13th, 1925.

### REVISED DRAFT MEMORANDUM OF EVIDENCE PROPOSED TO BE PLACED BEFORE THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

#### EXPLANATORY NOTE.

The following is the draft Memorandum of Evidence which appeared in the SUPPLEMENT of January 3rd, 1925, as revised by the Council after consideration of the replies of the meetings which have been held throughout the country. The alterations (other than merely verbal changes and some rearrangements in form) may be summarized as follows:

*Part I* is new.

*Part II—Para. 12:* Amplified to make clear that certain classes at present included in Health Insurance should be excluded.

*Paras. 13 and 14:* Altered to emphasize the opinion of the profession that all dependants should not be included, only the dependants of the poorly paid insured persons, and that the difficulties about including even these are great.

*Para. 18:* A sentence has been added to emphasize the need of protecting the interests of present Poor Law medical officers if the destitute are included.

*Para. 28:* Amended to make it clear that even if the scheme of the Memorandum were adopted it would for some considerable time probably be necessary to continue the services of whole-time venereal disease officers and tuberculosis officers.

*Para. 29:* Amended to show that the proposed maternity service is only for insured women and the wives of insured men, and otherwise to make the meaning clearer, particularly as regards the method of dealing with complaints and as regards the general procedure.

The remainder of the Memorandum and the Appendices are practically unaltered. A copy of the revised document is being sent to all non-members of the Association in order that they may use it at any local meetings of the profession that may be called.

#### PART I.

##### AUTHORITY OF THE BRITISH MEDICAL ASSOCIATION.

In presenting its evidence before the Royal Commission the British Medical Association acts in a dual capacity (a) as representing the organised medical profession in this country as no other body is in a position to do, and (b) as representing, under a special mandate, those practitioners, in this memorandum called Insurance practitioners, who are at the present time under contract with Insurance Committees for the provision of medical attendance to insured persons.

##### (a) As Representing the Organised Medical Profession in Great Britain.

The right, and indeed the duty of the medical profession as a whole to state its views on National Health Insurance will not be questioned. A system which for twelve years has provided domiciliary medical attendance by a method previously untried, to some 14,000,000 persons, must necessarily have a profound effect on medical practice and on the relations of the medical profession to the Government, to the community, and to the individual patient. And when it is noted that the Royal Commission is to report on "what, if any, alterations, extensions or

In 1914 the Association called a Conference of Representatives of Local Medical and Panel Committees. This has met every year since and is now a firmly established part of the machinery which the profession has devised to meet the new problems arising out of the National Health Insurance Acts. The Conference meets annually, or oftener if required; it contains representatives, elected by every Local Medical and Panel Committee, who together with their constituents, may or may not be members of the British Medical Association; it elects its own Chairman, and it has formally and repeatedly recognised the Insurance Acts Committee of the Association as its official mouthpiece in negotiations with the Government. It uses the staff and machinery of the Association

for its own purposes, and the Association has for some years been content to leave to the Conference the decision of all questions of details, regulations, and negotiations as regards remuneration.

## PART II.

### A SCHEME OF NATIONAL HEALTH INSURANCE.

The following sections of this Memorandum are not self-contained, and must be read in connection with each other.

1. The subject of this part of the Memorandum is the organisation of a national scheme of health insurance so far as medical services are concerned and the relationship of such a scheme to other services concerned with public health.

#### GENERAL.

2. At the outset it is desired to emphasize two general considerations. The first is that the organisation of a national health insurance scheme is not necessarily, or even probably, the best means of utilising limited resources for the promotion of national health. It is more than likely that there are a number of other directions in which, severally or collectively, a corresponding expenditure would produce an even more satisfactory return. Such are (1) proper housing, (2) town-planning with the proper provision of open spaces and recreation facilities, (3) smoke abatement, (4) a pure milk supply, (5) public-house reform and the regulation of the sale of alcoholic beverages, (6) the destruction of vermin, (7) education, (8) the aiding of medical research.

3. If, however, resources are sufficient, or if for other reasons it is deemed desirable to organise a national health insurance scheme, a second general consideration becomes of paramount importance, viz., that regard should be had primarily and constantly to the maintenance of health and the prevention of disease and not merely to provision for the alleviation or cure of morbid conditions when once they have arisen. To this end it is essential not only that the attention of all practitioners should be directed continually to the preventive aspects of their work, but that the existing machinery and medical officers of the public health service should be brought into close and organic connection with the insurance scheme.

4. A national health insurance system is understood to be one through which, in return for premiums paid or contributions made, participants are entitled to medical attendance and treatment, together with certain services ancillary thereto, and also to cash payments under certain conditions during ill-health or disablement. The medical profession, as such, is concerned only with the former class of these benefits, and with the giving of such certificates and reports as may be required in connection with the latter class.

5. The system established under the National Health Insurance Acts is on these lines. The medical profession has now had experience of it since January, 1913. At the beginning the success of the system was jeopardised by the facts that a large proportion of professional opinion was antagonistic to the system or to some of its important details, that sections of the insured population shared this antagonism, and that a lack of experience, combined with the overwhelming amount of work involved, led on the one hand to unsatisfactory practice arrangements, and on the other to very imperfect administrative machinery and methods. A little later the immense disturbance of the war and then of demobilisation prevented acquired experience from having its full practical effect, and it is during the last three years only that the system can be said to have been working in a really smooth and normal fashion. Indeed, some essential improvements came into force only at the beginning of 1924. Nevertheless, in the year 1922 both the Representative Body of the Association and the Conference of Representatives of Local Medical and Panel Committees declared "that the measure of success which has attended the experiment of providing medical benefit under the National Health Insurance Acts system has been sufficient to justify the profession in uniting to ensure the continuance and improvement of an insurance system."

6. A comparison of the conditions of practice among the classes to which insured persons belong, before and since 1913, leaves no doubt in the mind of the profession (a) that large numbers, indeed whole classes, of persons are now receiving a real medical attention which they formerly did not receive at all; (b) that the number of practitioners in proportion to the population in densely populated areas has increased; (c) that the amount and character of the medical attention given is superior to that formerly given even in the best of the old clubs, and immensely superior to that given in the great majority of the clubs which were far from the best; (d) that illness is now coming under skilled observation and treatment at an earlier stage than was formerly the case; (e) that, speaking generally, the work of practitioners has been given a bias

towards prevention which was formerly not so marked; (f) that clinical records have been or are being provided which may be made of great service in relation to medical research and public health; (g) that co-operation among practitioners is being encouraged to an increasing degree; and (h) that there is now a more marked recognition than formerly of the collective responsibility of the profession to the community in respect of all health matters. All these are immense gains and, though it is possible that some of them may not be wholly due to the establishment of the National Health Insurance scheme, they have certainly been hastened and intensified by that system.

7. On the other hand it has to be said that this very success had led, at certain seasons, and in times of widespread epidemic disease, to a strain upon its powers and resources which the profession has scarcely been able to bear; and the new conditions have resulted in a volume of regulations which must be observed, rules which must be obeyed, forms which must be filled up, and quasi-judicial machinery which it is desirable to avoid, to an extent which is regarded by insurance practitioners as oppressive, or even menacing, and which actually by itself deters some other practitioners from taking part in the service at all. The doctor is still an individual dealing with an individual patient and having his prime duty in this relationship; and in so far as his mind is seriously diverted from this by concern for other duties and relationships, and by fear of transgressing unwittingly rules and regulations made for other purposes, this is detrimental to his work and to the interests of those whom he is primarily serving. It is, of course, true that all citizens live and work under the restraining influence of law and social custom, and that members of the medical profession have also in mind the disciplinary powers of the General Medical Council and the ethical and other traditions of their profession, but in the world, even in the medical world, these are not so onerous, so omnipresent, so imminent, as to be a constant source of worry or distraction. Experience of the National Health Insurance system as at present established has led the profession to realise very vividly that its work may be made not more efficient but less efficient by a multiplicity of departmental requirements. Its aim is so to improve the system as to enable the profession to supply what the public needs under conditions which will make its services most easily and suitably available to the community.

8. It is the belief of the Association that in any national health insurance scheme certain broad principles with regard to medical benefits must be regarded as fundamental. These are:—

(a) The medical provision should be available for those persons, and only for those persons, who would be unable to obtain it without the help of the insurance scheme;

(b) The medical provision made for such persons should be, as far as possible, complete;

(c) The conditions under which the medical attention is given to the individual should approximate as nearly as possible to those of private practice;

(d) Medical representatives should be closely associated with the administration of the scheme, and as far as questions of purely professional conduct and treatment are concerned, judgment should be in the hands of purely professional bodies;

(e) Remuneration should be on such a basis as (i.) would produce an income not less than that which corresponding responsibility and work should produce in comparable private practice, regard being had to all relevant considerations, and (ii.) would not prejudice the continuous supply of the best type of practitioner.

9. If these conditions are not secured there will be grave danger (1) that the volume of work imposed upon the medical profession will be much greater than it can properly perform, at any rate for some time to come; (2) that much of the advantage of present professional feeling and tradition will be lost and the present relationship of doctor and patient be changed for the worse, to the prejudice of the patient; (3) that work under the insurance scheme will be regarded as of only secondary importance when compared with other branches of medical practice.

#### SECTION A. PERSONS TO BE PROVIDED FOR.

10. The first of the above principles raises at once the question as to the extent of the national health insurance service as regards the persons for whom provision should be made. Within the present scheme are included all persons under a contract of service, namely, (a) all manual workers, without any income limit and (b) non-manual workers with an income limit of £250 a year. Any such employed person who has a private income or pension of not less than 10s. per week, or is ordinarily and mainly dependent for his livelihood on some other person,

may claim exemption and is then required to make his own arrangements for medical attendance if his total income is above £160 a year (i.e., if his earned income is more than £131 a year or even less than this). Such persons are exempt from insurance in general but entitled to Medical Benefit. Further, certain whole classes of persons are excluded because, though under a contract of service, they serve under conditions which provide, by means of a superannuation scheme or otherwise, benefits considered to be at least equivalent to those of the national insurance scheme. On the other hand, certain persons who have been compulsorily insured for at least two years may continue their insurance voluntarily, even though they have ceased to be under a contract of service. These, however, are a relatively small number.

11. Questions which arise are (1) whether it is necessary to include within a national health insurance scheme all such persons as are at present included; (2) whether it is not at least equally necessary, from a national point of view, to include other workers who, though not under a contract of service, are in a like economic position; (3) whether those economically dependent upon such persons, should be included; (4) whether it is desirable to include within the same system of medical benefit those who are actually destitute, in this case of course with appropriate modifications as to contributions.

12. With regard to the first question, the Association, as will be seen in paragraph 15 of this Memorandum, is of opinion that certain classes of persons now included in the scheme should be excluded therefrom. It is impossible to resist the conclusion that provision for medical advice and treatment for certain of those referred to in the second and third questions is necessary in some form, and the Association is of opinion that the best way of making such provision is by help towards securing a family doctor or general practitioner, as can be done by an insurance scheme with a wide freedom of choice and conditions, rather than by state-paid or rate-paid medical officers or by the establishment of treatment clinics which must necessarily be restricted in their activities and their staffing. The Association also has no doubt that it is desirable to make provision for those referred to in the fourth question by means of the same general system.

13. It is recognised that the problems, even the medical problems, raised by these suggestions are by no means simple. While agreeing that, as a matter of national health, proper provision for medical advice and treatment should be made for the dependants of poorly paid earners, (though not for the dependants of all insured persons as at present), such earners themselves, and the dependants of those mentioned in the previous paragraph are not to be recommended as the best methods of making this provision, a considerable body of opinion within the profession fears that the difficulties may be so great as to make the suggestion of including even these persons in an insurance scheme impracticable. There is, however, a body of opinion in the profession which regards the provision of medical attendance on this class of dependants as being a most urgent need. On the financial side numbers would be formidable and there is no reason to suppose that the new entrants into an insurance scheme would be less costly than their predecessors. On the medical side the main difficulties would be found in (a) the amount of additional work imposed on the profession, and (b) consequential alterations in the conditions of practice in many areas.

14. There does not appear to be any exact estimate of the number of dependants, but assuming for the moment that the number of insured persons (say 15,500,000) remains the same as at present, and that to these be added persons in a like economic position and the dependants of both these classes, the additional number is possibly something like one and a half times as great—that is to say the total number would probably amount to 38,750,000 in all. It must be remembered that the demands on the profession under an insurance scheme would necessarily and properly be considerably heavier than those at present made by the same persons. This fact emerged during the early years of the operation of the National Insurance Scheme. The Association holds very strongly (1) that an extension on the scale indicated by the above figures is wholly unnecessary and would in practice be found almost impossible, and (2) that to cope properly with the new work which would be involved in any extension whatever of the insured population, to make it tolerable by the profession and to reduce the difficulties and liabilities in order to bring the whole problem within more measurable compass, it is imperative:

(a) to apply the first principle enunciated in para. 8 (namely the provision of medical service only for those persons who are unable to obtain it without the help of such a scheme) as strictly as is administratively possible;

(b) to make, concurrently with any such extension, certain arrangements tending to lighten the work.

15. The Association is of opinion:—

(a) That the classes of persons exempt from the scheme by reason of their contract of service including provisions giving benefits equal to those of the national scheme, should be extended to include others (e.g., bank and insurance clerks) not at present exempt;

(b) That persons with an unearned income of an amount per week not less than that prescribed for sickness benefit should be excluded;

(c) That any income limit (whether £250 a year or a lower amount) should be applied alike to the non-manual worker, the manual worker, and the voluntarily insured person;

(d) That unless a lower income limit than the present one is applied generally to insured persons a still lower income limit than that which is applied generally should be necessary with regard to inclusion of dependants.

16. It is not suggested that these income limits are exact criteria of economic need, but, in view of the considerable increase in the total of medical advice and treatment which would be entailed by the inclusion of dependants and others in like economic position, it seems necessary to draw the line of inclusion in the scheme as low as is reasonably possible, rather than as high as in other circumstances might be found desirable. The question of whether a contribution from the employer should be required for every one of his employees regardless of all, or any of, the suggested exemptions, is not a medical question and is not prejudiced by the above suggestions.

17. The Association is further of opinion that essential conditions accompanying any extension of a National Health Insurance scheme to include any dependants and others of a like economic status must be (a) a sufficiently adequate service of nurses available for home nursing; (b) the reduction to a minimum of all records and reports required from practitioners with regard to the new entrants, and a lightening of those required with regard to existing insured persons; (c) a revision of the matters which may be made the subject of complaint and of the methods of dealing with them on the lines of the suggestions made in a subsequent section of this memorandum. In suitable populous areas it would be desirable also to establish or continue infant welfare centres strictly confined to the instruction of mothers and the routine examination of infants and young children as to weight, etc., provided that these centres were kept in proper relationship to practitioners who should have reasonable access to the records of all cases under their individual care.

18. From the medical side only, the problem of the provision of advice and treatment for the poor person not under any contract of service, or for the necessitous person, is not specially difficult. The difficulties here are the details of finance and administration. If these can be overcome the profession is prepared to undertake the work in general accordance with the National Health Insurance Scheme here outlined. It is, however, essential that provision should in that case be made to preserve the interests, as to superannuation and otherwise, of all existing medical officers affected by the change.

#### SECTION B. EXTENT OF PROVISION TO BE MADE.

19. The second of the main points is that the medical provision made for all persons included in the scheme should be, as far as possible, complete. Under the present scheme the medical advice and treatment provided is, broadly, such as can reasonably be expected from general practitioners as a class. Other services publicly provided under the auspices of local authorities are also available—certain pathological facilities, treatment for tuberculosis and venereal disease, and for certain infective fevers, the treatment of certain conditions of children of school age and provision in connection with maternity and infant welfare. Moreover, some Approved Societies make contributions to some of their members toward the cost of a few other treatments, e.g., dental, ophthalmic, or institutional. These benefits are, however, available for only a small proportion of insured persons, although all pay the same premiums. A further small provision for possible consultative advice by or through the regional medical officers, is, so far, scarcely at all developed.

20. It is desired to make all such services and benefits an integral part of the insurance scheme or to bring them into proper relationship thereto, so that they may be available for all persons included; and to extend the provision so as to include complete consultant and specialist advice and treatment, full laboratory facilities for clinical purposes, residential institutional treatment so far as possible with limited accommodation, dental advice and treatment, such ancillary help as can be given by nurses and masseurs, and an ambulance service—in addition to the general practitioner advice and

treatment and the provision of necessary drugs and appliances which is at present the main provision made. The Association is of opinion that all these benefits should be equally available to all insured persons alike, regardless of their membership of any particular society.

21. It seems necessary here to emphasise that when "general practitioner advice and treatment" is spoken of, the phrase does not indicate anything of an inferior character. In their own way and for their own purposes, such services "as can reasonably be expected from general practitioners as a class" are fully as important, as scientific, as highly skilled, as those which are provided by other practitioners in more special and restricted lines of practice. Practitioners, whatever their sphere of practice, may be relied upon to devote to their work all the knowledge, care and skill which they have; the distinction is mainly one of range. Experience and skill in certain directions can only be acquired by those (some general practitioners included) who are able to direct special attention to a particular branch of practice or class of case, or to the performance of certain surgical operations or manipulations. It is desirable to secure all these different kinds of skill for the participants in an insurance scheme, without implying that one kind is superior in itself to another.

22. It is obvious, as is the case at present in connection with the provision of drugs and appliances, that persons who under the scheme would be eligible for all the additional services could not be put into a position to claim them whenever they wished. Otherwise demands might be made which would be disadvantageous medically and ruinous financially. With slight modification in one or two instances these services should be available only on the recommendation of the general practitioner responsible for the patient. This rule, however, might require safeguarding in two directions. On the one hand it is conceivable that a practitioner might make unreasonable or excessive use of these facilities, and accordingly practitioners might be (a) required to notify the administrative authority on recommending a patient for these extra services, and (b) liable to explain to a professional committee the reason for any apparently excessive use. On the other hand there might be cases, as in private practice, in which there might be a difference of opinion between practitioner and patient as to the need for the extra service, or cases in which a society or other body responsible for cash payments during sickness might make a request for further special advice, and accordingly provision might be made for an official referee to decide the matter in such cases where necessary.

23. The cases calling for a modification of the general rule that services should be available only on the recommendation of the general practitioner responsible are (a) the prescribing of any necessary drugs or appliances, or the using of other extra services by the consultant or specialist to whom the patient has been referred not for consultation only but for the carrying out of some special investigation or treatment; and (b) the direct application by the patient to a dental surgeon or dentist for dental treatment. In the latter case some safeguards would be required for dental services of specified kinds or for any procedure estimated to involve expenditure beyond a stated amount.

24. The medical personnel of the consultant or specialist service should consist of those registered medical practitioners who satisfy certain criteria as to status and who express their willingness to accept service within each area. These criteria should be those at present laid down in the Medical Benefit Regulations and elsewhere for a similar purpose. These are:—

(a) That he has held hospital or other appointments affording special opportunities for acquiring special skill and experience of the kind required for the performance of the service rendered, and has had actual recent practice in performing the service rendered or services of a similar character; or

(b) That he has had special academic or post-graduate study of a subject which comprises the service rendered, and has had actual recent practice as aforesaid; or

(c) That he is generally recognised by other practitioners in the area as having special proficiency and experience in a subject which comprises the service rendered.

The decision as to whether any individual practitioner desiring to serve in a consulting or specialist capacity does in fact satisfy these criteria should be in the hands of a local professional committee. Any practitioner excluded by the decision of such a committee should have the right of appeal to a small *ad hoc* professional committee representing a wider geographical area. From a list of consultants and specialists so compiled a practitioner, in agreement with his patient, might choose any individual considered most suitable for the particular case.

25. In normal circumstances, or whenever possible, such consultations would take place or such specialist services would be given, either at the consultant's rooms, or at the practitioner's house or surgery, or at the patient's house. The conditions in some localities, however, might make desirable the establishment of special premises for this purpose, and such premises might in some cases even be the out-patient department of a hospital. Wherever such consultative or specialist clinics were established attendance would have to be given by the medical officers at fixed times, the clinic should be available for the purposes of medical education, particularly post-graduate, and general practitioners not on the specialist list should be eligible for service as clinical assistants.

26. Among the detailed arrangements that must be made for the conduct of such a service is the important one for exchange of opinion and co-operation in treatment between the general practitioner responsible for the case and the consultant or specialist to whom the patient has been referred for advice or treatment. It is desirable that a system should be adopted whereby the practitioner referring a case would furnish the consultant by some method with information of the previous history and points on which advice is specially desired, and the consultant would furnish the practitioner, with information as to the results of his examination and any treatment given or future treatment advised. Provision might be made for insisting upon actual personal consultation between practitioner and consultant where either of them considered this necessary. The primary responsibility of the general practitioner in charge should be preserved in all cases.

27. The relation of certain existing clinics or treatment centres, provided by local authorities under statutory powers, to the suggested arrangements must be considered. Obviously in so far as persons provided for by these clinics come under a health insurance scheme, and so far as the treatment provided thereat is either general practitioner treatment or such as can normally be given by a consultant or specialist elsewhere, they would no longer be required. If they remained—as in many cases no doubt they would—their functions would be somewhat as follows:—(a) they would be centres for education in health matters; (b) they would be places at which practitioners might make appointments with their patients when necessary for special purposes; (c) they would be specialist clinics for persons under the insurance scheme where consultations elsewhere were not possible; (d) they would be available for public provision for such persons as did not come under the insurance scheme when such provision was still held to be necessary for certain purposes.

28. It is likely that for some time to come it would still be necessary to continue the appointment of whole-time officers dealing with tuberculosis and with venereal diseases.

29. The relationship of maternity work to the health insurance scheme requires special mention. It is contemplated that complete provision should be made for this as part of the medical service for insured women and the wives of insured men. Provision should be made, in addition to a cash payment, whereby attendance at confinement and during the puerperal period together with special examination and supervision during pregnancy would be brought within the scope of the scheme. Certain conditions are, however, essential if this is to be done: (1) any insurance practitioners should be at complete liberty to undertake or to decline this work without any administrative detriment to his interests otherwise, (2) any complaints as to treatment in connection with this work must be referred to a solely professional committee on which the local administrative authority should be represented by its medical officer; (3) there must be everywhere an efficient service of registered midwives, (4) there should be provision for institutional treatment for serious cases of ante-natal complications, for cases requiring major obstetrical operations, for cases where isolation and treatment of septic infection is specially indicated, and for cases where the home conditions are very unsuitable or dangerous for confinements; (5) any registered practitioner should be at liberty to place his or her name upon the list for maternity purposes only. Provision for a woman within the insurance scheme would thus be for: (a) medical examination (not compulsory), and supervision during pregnancy; (b) attendance by a registered midwife during normal labour and during the puerperal period (the ideal being that both a midwife and a doctor should be provided, but where the scheme cannot provide for both in respect to normal labour the interests of the patient would best be served by the provision of a midwife); (c) attendance by the practitioner of her choice during labour and the puerperal period when his attendance is requested by the midwife under defined conditions, or when, as a result of his examination during pregnancy he has declared his personal attendance to be necessary. Professional services under these headings would be remunerated,

as in the case of the other extra services, by a special scale of fees. The procedure would be for the insured woman at an early state of pregnancy, to choose her doctor; for the doctor so chosen to make, with her consent, a suitable examination during pregnancy; for the midwife to be notified as to the doctor to be called in, and as to the conditions under which she must ask for his services. The consultant and specialist service would be available also in this connection.

30. The provision for a clinical laboratory service stands on a somewhat different footing. There are advantages in such a service being associated with research work; and suitable laboratories are as a rule connected with universities or hospitals, sometimes the larger voluntary hospitals, sometimes hospitals for infectious disease established by local authorities. When, however, routine investigations are undertaken by a university laboratory, such routine work should not be allowed to interfere unduly with teaching and research which are the proper work of a University Department. It is desirable that the necessary laboratory work should be divided between a relatively small number of large central laboratories and a larger number of small laboratories. At the former, investigations requiring special facilities or apparatus or those which can be carried out with greater accuracy, uniformity and economy when large numbers of specimens are dealt with would be made. At the latter, tests not involving the use of elaborate or exceptional apparatus would be carried out. Highly trained pathologists would be required for most of this work, and in practice it would be impossible and undesirable to restrict their activities to work required by the National Health Insurance scheme alone. Under these circumstances it seems desirable that laboratories should be established and maintained under other auspices, and that a suitable financial contribution should be made to them from the National Health Insurance fund in respect of the work which they do for persons included within the scheme. Some approved clinical laboratories under private management might be recognised for the same purpose. There are a number of cases, moreover, in which satisfactory results can be expected only if it is possible to provide pathologists to visit patients in their own homes and take the specimens required for examination. It is advisable to arrange for this, as well as for exchange of opinion between clinicians and laboratory workers.

31. For residential institutional treatment arrangements on much the same plan would probably be found most suitable, at any rate for a considerable period of time. There would be available the voluntary hospitals of various types, the hospitals for infectious disease, and the tuberculosis sanatoriums established by local authorities, and the present poor law hospitals. In use none of them could be restricted to persons under the insurance scheme alone, and the total accommodation in them would be insufficient in many areas. The right of insured persons to admission would thus be limited in accordance with arrangements made with the authorities governing particular hospitals or institutions. A copy of the hospital policy of the British Medical Association will be attached hereto, with those provisions marked which have special applicability to any such arrangement made on behalf of participants in an insurance scheme. This makes it clear that when use is made of voluntary hospitals or other charitable institutions for the treatment of insured persons, either as in-patients or out-patients, the cost of such treatment should not be a charge on the ordinary funds of the institution but should be defrayed in full out of the Medical Benefit Funds of the Insurance Acts, taking into consideration that the charge should include a percentage for the remuneration of the Visiting Staffs of the hospital in accordance with paragraph 31 of the British Medical Association Hospital Policy. The position of convalescent or rest-homes requires special consideration in this connection.

32. Before leaving this section it may be as well to point out that even within the scope of general practitioner treatment at present the provision for the needs of insured persons is not complete. Although there is complete provision for the supply of any drug or medicine which the practitioner in charge of a case may consider necessary (with due provision against sheer extravagance) there is considerable restriction as to the appliances which may be ordered. No doubt the reason for this is financial, but it would be a great advantage to allow all appliances necessary for the sick person to be supplied. In the case of some such appliances it might be possible to arrange for their loan to the insured person where they are required only temporarily.

33. One other contingent suggestion may perhaps be made. If it should be found desirable to continue to require payments from employers in respect of certain of their employees who were not included in the insurance scheme as a whole (i.e., exempt persons but for whom a card has to be stamped by the employer), it might be found possible and advisable to give

such employees the benefit of some or all of these extra services by reason of such contributions.

#### SECTION C. REGULATIONS AND TERMS OF SERVICE.

34. A third main principle is that the conditions under which medical advice and treatment is given, whether by general practitioners or consultants, should approximate as nearly as possible to those of private practice, and should preserve within wide limits professional customs and traditions. These traditions and conditions must, of course, to some extent be modified by the facts that the scheme is based upon an insurance plan, and that under the scheme the practitioner undertakes certain responsibilities not to his patient alone but to the State and to societies or bodies administering cash payments during sickness or disablement, but no unnecessary requirements should be imposed either upon the insured person or the practitioner.

35. An essential point is that, as is the case at present, any registered medical practitioner shall be able to participate in the service as a right if he is willing to accept the conditions, and until his continuance in the service has been properly adjudged to be detrimental to it. Unless this be so, a large part of their possible field of work would be automatically cut off from practitioners who have complied with those tests which have been recognised by the General Medical Council, in this respect the statutory governing body of the profession, as permitting entry to the profession. It seems to follow as a corollary from this that the conditions laid down for acceptance should be as little complicated and onerous as possible, so that as large a number as possible shall be willing to engage in work under a national health insurance scheme. This would be an advantage to the profession, to insured persons and to the public health alike. It is believed that the suggestions in this and the following section would tend, if adopted, to increase the number of practitioners willing to take part in this work.

36. The main fact of daily professional work is the intimate and confidential relationship which must necessarily arise between patient and doctor and without which, in a large number of instances, results must be far less satisfactory than would otherwise be the case. A very important factor in preserving this relationship is the right of a patient at any moment to seek the services of another practitioner and the right of a practitioner to intimate that he wishes no longer to be responsible for a particular case. All questions of supposed neglect or lack of success or improper behaviour on the part of a doctor, and of unreasonable conduct on the part of a patient may be solved very simply by the exercise of these rights, and there is no reason why, speaking generally, in reference to such matters, specific rules accompanied by penalties should be imposed on insured persons or special provision be made for complaints against practitioners, if a similar freedom of choice can be exercised. This freedom has been secured absolutely for insured persons under the regulations which came into force in 1924, but the corresponding freedom of the practitioner is still unnecessarily restricted. It should be equally absolute, except that he should not abandon his responsibility for an actually ill person until other attendance has been secured. In the circumstances indicated it is obvious that the desirable thing to do is not to keep doctor and patient tied together as long as possible, but to make other arrangements as rapidly as may be, and to do this with as little unpleasantness or recrimination as possible. There can be no objection, of course, to a statement in general terms as to what constitutes reasonable conduct in certain respects on the part of a patient, or what are in general the duties which the doctor undertakes to perform.

37. The conditions of an insurance scheme also make certain requirements or provisions necessary which are not needed in the conditions of private practice. These, however, though important, should be few. An insured person should be required (1) to seek acceptance by a doctor before occasion for medical treatment arises; (2) to claim treatment as an insured person, by the production of a medical card or otherwise, on at least the first consultation of each series. Failure in either of these respects should render the insured person liable to a penalty or to the payment of a fee, for otherwise an essential principle of insurance is violated or the doctor is placed in a serious difficulty as to his duty. An insurance practitioner should be liable to a penalty for (1) wilfully charging a fee for any service which he had undertaken to render as part of the insurance service; (2) such general conduct as is held to be detrimental to the interests of the service.

38. An insured person, moreover, has an obvious grievance if he experiences undue difficulty in securing acceptance by any practitioner in his district at all, unless he has brought this about by placing himself in charge of an unqualified person and whilst he continues in such charge; and

the arrangement made with the practitioners of an area must provide against an insured person being placed in this position.

39. Beyond his relationship to his patient as medical attendant the practitioner undertakes to keep certain records and make certain reports and also to furnish certain certificates. Statements made in such records, reports, or certificates about a patient's condition are matters of professional judgment, and, if honestly made, should not render the practitioner liable to any complaint beyond that to which all practitioners are liable in all their professional work, but wilful failure to keep records, make reports, or furnish certificates on the occasions on which the practitioner has undertaken this duty, or the making of wilfully false statements in such documents, may well be the subject of serious official action.

40. If official complaints against an insured person were restricted to his failure to take action in the two ways indicated in paragraph 37; and if official complaints against practitioners were restricted to the cases indicated above, it is probable that such complaints would not be numerous and liability to them would be recognised as on the whole just. It is probable, too, that the machinery at present provided for dealing with such complaints would, with some minor adjustments, be considered to be not inappropriate in the majority of cases. It is suggested, however: (1) that all complaints against a practitioner should in the first instance be sent to the Chairman of the Local Medical Committee and the chief administrative medical officer of the local authority (mentioned in paragraph 46); (2) that only such as could not be settled by them with the acquiescence of both parties should proceed further; (3) that questions of general conduct, detrimental to the service, or of giving false certificates should be reported upon in the first instance by the Local Medical Committee; (4) that an appeal to the Courts should be possible not only on the ground of improper procedure as at present, but also on the ground that the penalty inflicted was out of proportion to the offence; (5) that in the case of proposed removal from the service the practitioner should have the right of appeal to a duly constituted central professional committee, and that the Minister of Health, in cases where this right was exercised, should not be able to remove the practitioner from the service unless the central professional committee advised this course.

41. The circumstances of medical practice are so diverse in different parts of the country that any absolutely uniform regulations or terms of service are very difficult of application in some respects and in some areas. Particularly do the conditions in sparsely populated districts need special consideration. It is, on the other hand, undesirable that similar conditions in different geographical areas should be differently dealt with, and, indeed, that there should be any unnecessary variety in the conditions or terms under which practitioners serve. It is suggested, therefore, that in the official regulations and terms of service there should be in some sections alternative provisions which might be adopted in certain districts or even in individual cases. Evidence as to special conditions in (a) sparsely populated rural areas, and (b) certain colliery areas, will be found in Appendices I and II.

42. There is one anomaly in the arrangements for the provision of medical benefit created by Section 15 (4) of the 1911 Act (Section 24 (4) of the 1924 Act) which the Association is of opinion should now be rectified. The Section in question of the 1911 Act recognised certain medical aid institutes existing at the passing of the Act as agents for the administration of Medical Benefit (including the provision of any necessary drugs and appliances) for their members. The term "Medical Aid Institute" is a generic title which covered Friendly Society Institutes, Workmen's Medical Aid Associations, Workmen's Medical Funds and certain Provident Dispensaries—all now known under the style of "Approved (15 (4)) Institutes." It is believed that all these institutions employ whole-time medical officers paid by a salary, whose appointment and control is entirely in the hands of the governing body of the institute—a purely lay committee. The Association is of opinion that the standard of treatment given by these institutions is not equal to that given by the insurance service as a whole; it is certain that the great majority of medical men decline to take service under the conditions laid down by these institutions, and it is difficult to argue that they supply any such need of the community as justifies their being placed outside the general scheme of administration of medical benefit.

#### SECTION D. ADMINISTRATION.

43. Two of the main principles to be satisfied in the administration of a National Health Insurance scheme seem to the Association to be these: (1) that the medical benefits in the widest sense (including the "treatment benefits" at present provided and administered by some Approved Societies) should be regarded as a health service and administered along with

other health services, distinct from the administration of any cash benefits, which should themselves be administered either separately or along with other cash benefits available from other schemes of National Insurance, and (2) that in the administration of the health services provision should be made for participation of the medical profession to an adequate extent. In Appendix III will be found a statement as to points in connection with one of the "Additional Benefits," namely, Ophthalmic Benefit.

44. The central administration of all health services should be under the control of the Ministry of Health, and the local administration of all these services should be in the hands of a local authority established *ad hoc*, or acting through a statutory Committee constituted in accordance with schemes—all of which should provide for a proportion of membership of persons of experience in health matters, including representatives of the medical profession. Such committees would be analogous to the existing statutory Education Committees of local authorities. It is recognised that existing Local Government areas are in many cases not ideally the best for purposes of health administration, and that altogether new areas centred in each case round a considerable town, would be more satisfactory for purposes both of health and of education. Of existing authorities, however, it is probable that County Councils and County Borough Councils would be found the least unsuitable, though in a few cases it might be preferable to group a few Borough or Urban District areas.

45. In any case such unification of medical services as those contemplated in this Memorandum would, in such an administrative system involve the disappearance as such of Insurance Committees and the transfer of the health functions of the Poor Law Guardians. It is certain, however, that many of the members and officers of these bodies would be indispensable for the work of the unified authority.

46. Each such Authority would have a Chief Administrative Medical Officer, who would no doubt in most cases be the existing Medical Officer of Health. In each area there would be also a Statutory Local Medical Committee elected or appointed under a scheme which would ensure that it was representative of all kinds of medical practice in the area. Such a medical committee would take the place of both the existing Panel Committee and the existing Local Medical Committee, and like the former of these but unlike the latter, would have funds provided for administrative purposes. The duties of this Committee would be to appoint the representatives of the medical profession on the Local Health Committee and on any other local committees containing such representatives, to conduct any negotiations with the local health authority on behalf of the profession, to advise that authority on purely professional matters and to perform any other statutory duties imposed upon such a Medical Committee. The Medical Committee should have the right to present its view not only to the Local Health Committee but also to the Ministry of Health and to the public. A separate Dental Committee would probably be required.

47. The administration of the cash benefits (sickness disablement, maternity) does not primarily concern the medical profession as such. Practitioners are, however, brought into close and important relationship thereto by reason of the facts: (1) that they have to give medical certificates on which to a large extent the payment of these cash benefits depends; (2) that they often find their patients in doubt, difficulty or even distress with reference to these payments; (3) that they, through the Insurance Committees, are largely dependent on the bodies which administer these benefits for the correctness or otherwise of the lists of insured persons for whom they are responsible.

48. Evidence of serious imperfections in the administration of Approved Societies both in notifying Insurance Committees of the enrolment of insured persons and of the suspension of their members from medical benefit, and in the payment of sickness benefit to their members, is continually coming to the notice of practitioners in their daily work, but except as to one matter on which there are official statistics of great importance, the Association does not wish to stress this. Doubtless, as in the corresponding matter of the imperfections of medical attendance and treatment, a considerable proportion of the complaints are vague and incapable of being substantiated, or are really due to faulty action on the part of the insured persons themselves. Doubtless, too, there are a considerable number of agents of large societies and a number of part-time officials of small societies who are unable to understand, or do not take the trouble to understand, the regulations under which they work or the instructions of their superior officers, just as there are some practitioners who will not read or consider memoranda or communications addressed to them. Doubtless, again, as in the case of medical attendances, the proportion of cases in which there is cause

for complaint is quite small in relation to the total number of occasions on which complaint might possibly have arisen. Nevertheless it is distressing to doctor as well as to patient to witness cases in which actual want arises and delay in recovery ensues owing to the non-payment or the delay in payment of benefits to which the insured person appears entitled; and there is much loss of valuable time in explaining to such persons what they should do in order to secure what they believe to be their rights or to what quarter their complaints should be addressed.

40. The matter of the delay of Approved Societies to notify promptly the fact that members have passed out of medical benefit or issue orange slips notifying suspension from medical benefit is, however, serious. The following extract is from the official Memorandum (C.I.C.I.) issued to Approved Societies by the Central Index Committee in March, 1923:—

"21. *Delay in issue of Orange Slips.*—The suspension from medical benefit which requires to be notified by the issue of an orange slip arises out of circumstances which should be known to the Society some considerable time before the suspension is due to take effect, and in the case of employed contributors usually about six months before that date. The instructions require that the Society should issue the orange slip as early as possible in the half-year at the close of which the member is due to be suspended. This, again, is no mere formality; it is necessary in order that the orange slip may be forwarded to the Insurance Committee before the suspension actually takes effect so that the member may be removed from the doctor's list immediately he ceases to be entitled to benefit. Doctors are credited on the numbers upon their lists at the beginning of each quarter; and it follows that if the Insurance Committee is unable to remove a suspended member from his doctor's list by the first day of the ensuing half-year, the doctor is credited for a further quarter at least in respect of that member, while the member himself may enjoy a period of medical benefit beyond that to which he is entitled.

"22. Notwithstanding, however, the practical importance of the prompt despatch of orange slips, much delay has been experienced by the Central Index in receiving them from Societies. The orange slips received notifying suspension on 30th June, 1921, for example, numbered 275,000, of which no more than 100,000 were received in time to permit of their being dealt with before the date of suspension, the balance of 175 per cent. of the persons concerned being still entitled to doctors after ceasing to be entitled. In the case of suspensions taking effect on 31st December, 1921, 474,000 orange slips were received, of which 250,000 only were in time to be dealt with by the date of suspension; while of the suspensions taking effect on 30th June, 1922, 326,000 were received, of which 223,000 alone could be dealt with before the date of suspension."

"23. It will thus be seen that in practice a large proportion of the orange slips issued are despatched too late to be made effective by the date of the suspension which they are intended to notify; and the consequence of this delay is, as already indicated, that hundreds of thousands of insured persons are in a position to obtain benefit beyond the period for which they are entitled to receive it, while credit for them is unavoidably given to the doctors concerned for a full quarter at least beyond the date of suspension, irrespective of the date when the numbers are actually taken off the doctors' lists. Some substantial improvements can reasonably be expected in this connection; and apart from the consequences just indicated, the Central Index Committee think it necessary to point out that delay of this kind is bound to increase the administration expenses of the Index. If all orange slips were forwarded promptly by each Society in the early part of the half-year at the end of which suspension is due, or in the case of large societies issued in equal instalments at regular intervals throughout that half-year, the heavy work of handling them and passing them on to Insurance Committees could be overtaken with an even load of work. If, however, receipts of orange slips are, as at present, congested towards the end of that half-year, extra expense is incurred through the distraction of the current work or the employment of extra staff to cope with the congestion."

\* The figures in this paragraph relate to England.

This shows that in a period of eighteen months as the direct result of imperfect administration on the part of approved Societies there were 503,000 persons whose doctors were liable to attend in respect of whom no contribution was forthcoming, and there are figures showing that in Manchester

alone there were such persons actually receiving treatment as follows:—During the last two quarters of 1921, 252; first three quarters of 1922, 750; whole of 1923, 1,160; and during the first three quarters of 1924, 706.

50. The profession regards the question of medical certification as of the highest importance, and looks upon the issue of a false certificate as one of the gravest offences of which a practitioner can be guilty. There has, no doubt, from time to time, been a certain amount of lax, or distinguished from wilfully false, certification on the part of some practitioners, and some disregard of certification rules which, since they were in force, should have been strictly obeyed. In practice, however, it is difficult sometimes to obey all the rules quite strictly without doing some injustice to the insured person, and many of the conclusions which have sometimes been drawn by the officials of Approved Societies from an examination of large numbers of medical certificates or from the results of reference to Regional Medical Officers are erroneous, due often to very natural misinterpretation or misunderstanding. It is recognised that bodies responsible for the administration of cash benefits have a right to be consulted with regard to the arrangements for certification and to criticise the working of such arrangements, and the Association is prepared, should the Royal Commission wish it, to go more fully into the question of certification and to reply to any allegations which may possibly be made with regard thereto; but it appears that, in the main, medical certification in relation to sickness benefit is remarkably well done, and certainly an immense amount of trouble is taken to do it conscientiously and accurately, in spite of some failures.

51. Some alterations in the forms of certificate and of the Certification Rules and arrangements would conduce to the easier and more harmonious working of the system, and would be for the convenience alike of doctor and patient, without seriously interfering with the rights of the bodies administering cash benefits. For example, the phrase "incapable of work" used in the Acts and therefore necessarily repeated in all certificate forms is misleading and inaccurate if the words are given their ordinary significance; and certificates containing this phrase can be signed honestly only because the words are now understood to have a technical meaning, which, however, needs a pamphlet to set forth accurately. It is desirable that this phrase should be altered. With this exception the form of the first and of the final certificates might remain as at present, and it is probable that a First Intermediate Certificate may properly be required under the same conditions as now; but with regard to other intermediate certificates it is suggested (a) that they should simply state that the practitioner has seen the patient on a particular day and that the patient remains unfit for work; (b) that the interval between the issue of such certificates should be at the discretion of the practitioner provided that such interval was not greater than 14 days in the case of Sickness Benefit nor than 42 days (or in rural areas three months) in the case of Disablement Benefit; (c) that the practitioner should be able in the former case to apply for permission to make the interval longer than 14 days, and that the body administering Disablement Benefit should be able in the latter case to ask that the interval should be made shorter than 42 days or three months, as the case may be; (d) that the arrangements for special intermediate certificates dealing with absence from home should be more elastic both as to the period of illness at which such certificates may be issued and as to the length of time for which they should be available.

52. In the event of the complete separation of the administration of medical benefit from that of cash benefits which is suggested, the method by which these cash benefits shall continue to be administered is not the concern of the profession. Many practitioners, however, hold the belief, based on experience, that this administration is likely to be more satisfactory and sympathetic in the hands of certain classes of Approved Societies than in the hands of a large State organisation or committee of a local Government Authority. If it is determined that Approved Societies shall continue with this administration as one of their functions it is suggested that there should be certain requirements which all such societies should meet. They should (1) be of such a size as would constitute a properly insurable group; (2) be of such a character as to have such financial arrangements made for them by consent as will not vitiate a uniform insurance scheme; (3) be of sufficiently uncomplicated constitution so as not to put their members at a disadvantage; (4) be obliged to classify all their members on a territorial basis; (5) be in uniform as regards their rules for the conduct of insured persons.

53. The profession is completely convinced, in consequence of intercourse with insured persons over a period of twelve years, that Approved Societies, as at present constituted, do not as a whole in any sense represent insured persons, their

wishes or opinions. For the most part insured persons take not the slightest interest in the work of their Societies, and very often do not know the name of the Society to which they belong. This indifference is probably inevitable in the case of the larger Societies, and of the great majority of insured persons, and does not necessarily indicate any lack of interest or ability or zeal on the part of the principal officials of such Societies.

#### SECTION E. REMUNERATION.

54. The remuneration of members of the medical profession working under the National Health Insurance scheme should be determined on its merits by negotiation between the Ministry of Health on the one hand and a central body representing the profession on the other. Such central body might most properly be the Council of British Medical Association, representing, as it does, all branches of the profession through its Divisions and Branches, and the Local Medical Committees of the country through its Insurance Acts Committee. The Association is strongly of opinion that the remuneration of the general practitioner service should be by a capitation system, though local option might be allowed as now in the distribution of the amount allotted in each area. The remuneration of consultation and specialist work, on the other hand, must necessarily be by tariff fees according to the variety of service rendered, or in some cases by seasonal fees according to the time given and character of the work done.

55. The amount of the central practitioners fund must necessarily be arrived at by a somewhat elaborate actuarial calculation since it is impossible accurately to count the insured population day by day. The distribution of this pool to the different areas, too, must be made by a small expert Committee who will take account of all relevant facts. In the past there have been great difficulties in both these calculations, and it is desirable that the profession should be completely assured that any margin of error is reduced to a minimum.

56. The principle on which the amount of the remuneration should be established is that it should in total compare not unfavourably with that which should be forthcoming from similar responsibility and work in private practice of a like nature among the same class of persons, allowance being made for security on the one hand, and on the other hand for work done not primarily for the individual patient but for the State or public body.

57. The actual amount of the capitation fee on which remuneration for the general practitioner service should be based has been so recently and so fully argued, before the Court of Enquiry in January, 1924, that the profession has no wish to re-open the matter at the moment. They are, however, convinced (1) that the capitation fee of 9s. is still too low to be a proper remuneration for the responsibilities undertaken and work done under the insurance scheme; (2) that the extra amount allowed for rural conditions requires reconsideration. The exact determination of this matter, however, and the appropriate tariff of fees for consultant and specialist services must depend largely upon the nature of the insurance scheme recommended by the Royal Commission and enacted by Parliament. It is, therefore, not possible with advantage to carry it much further at the present time.

#### APPENDIX I.

##### MEMORANDUM AS TO SPECIAL CONDITIONS OF INSURANCE PRACTICE IN RURAL AREAS AND THE EXTRA REMUNERATION CALLED FOR TO MEET THEM.

1. Any consideration of the special conditions of rural practice was specifically excluded from the Reference to the Court of Enquiry into Remuneration in January of last year. It therefore becomes necessary to go somewhat fully into this aspect of the question before the Royal Commission. The importance of the matter to the profession is evidenced by the fact that in 1923 of 12,711 insurance practitioners there were 5,649 (40 per cent) who claimed mileage, and therefore to some extent were practising under rural conditions.

2. There are certain undeniable peculiarities in these conditions to which the attention of the Ministry has already been drawn, and which have been acknowledged by them as worthy of consideration. They may be summarised as follows:—

- (i.) The list of a practitioner in a sparsely populated district must necessarily be smaller on the average than that of one in a town;
- (ii.) The cost of travelling and the time occupied in travelling is much more in the country than in a town;
- (iii.) The facilities for lightening the work of the practitioner (e.g., nursing and hospital facilities) are less in the country than in the town;

(iv.) The proportion of visits to attendances at the surgery is higher in the country than in the town, and the time occupied in rendering service is longer;

(v.) The necessity to engage a *locum tenens*, even for a short absence from home, whether for holiday, study, or professional business, presses hard on the country doctor, since deputising arrangements such as are the custom in the towns, are impracticable;

(vi.) The absence of day schools and of practically any higher education facilities in the more rural districts adds very materially to the country doctor's domestic expenses.

3. With regard to (i.), the average number of insured persons on the lists of the doctors who claim mileage is 697, that on the lists of all other doctors is 1,200. The doctors claiming mileage include many town practitioners who have a few patients in the country, and if these were excluded it is probable that the genuine country practitioner would be found to have an average of between four and five hundred, and that this list is incapable of increase. It may fairly be contended that a list of 500 people in a sparsely populated district takes at least as much time to work as one of a thousand in a town.

4. With regard to (ii.), since 1920 a mileage grant has been established purporting to cover the cost in money and time of travelling beyond two miles from the practitioner's residence, and a comparatively small addition was made in 1924 to meet the other conditions enumerated.

5. There is no doubt that at present owing to the unattractive financial conditions, rural practices are being abandoned in certain parts of the country. The difficulty is not confined to Great Britain and is perhaps inevitable, but if it is desired to retain efficient doctors in the country, it is absolutely necessary that their emoluments should be such as will enable them to maintain in all essentials a suitable standard of life.

6. The best solution would seem to be the retention of the present system of a general capitation fee for the whole profession with augmentations to meet the special requirements of the rural practitioner.

7. Remuneration as expressed by the capitation fee has been approached in the past chiefly from two directions: (1) the value of work done for insured persons as measured by the time occupied in the services rendered—a certain net income for an average practitioner in full work being assumed—and (ii.) the value of services rendered as estimated by the fees commonly charged by general practitioners. Both these lines of approach would seem to point to the need for a supplementary fund for practitioners in rural districts, for (i) the time occupied in the same services is definitely greater under country conditions for the same number of patients, and (ii.) the fees charged both for visits and attendances at the surgery in country practices have always been of necessity higher than those in towns—a fact apparently left out of consideration in 1911, when the matter was investigated chiefly on urban data.

#### APPENDIX II.

##### MEMORANDUM AS TO SPECIAL CONDITIONS IN COLLIERY AREAS OF SOUTH WALES.

1. Section 16 (3) of the 1911 National Health Insurance Act (24 (3) in the Act of 1924) authorises the Insurance Committee to require any person whose income exceeds a limit to be fixed by the Committee and to "allow any other persons in lieu of receiving medical benefit under such arrangements as aforesaid, to make their own arrangements for receiving medical treatment and attendance . . . and in such cases the Committee shall . . . out of the funds out of which medical benefit is payable contribute . . . sums not exceeding in the aggregate the amounts which the Committee would otherwise have expended in providing medical benefit for them."

2. In practically every area with the exception of South Wales this section of the Act has been taken to apply to individuals, but the Insurance Committees of Monmouthshire and Glamorgan have taken advantage of it to hand over the capitation fees to bodies of workmen who have set up "Schemes" for the purpose of giving medical attendance by salaried doctors to the workmen and their families. The money for the families is obtained by deductions from the men's wages supplemented by the money provided from Insurance funds under the above-mentioned section of the Insurance Act. The medical profession has always protested strongly against what it believes to be an abuse of the section, on the ground that these Schemes are an evasion of the intentions of the Act which contemplate that the normal system will be the panel system, whereas these Schemes are worked on a whole-time salaried system.

3. The Schemes are invariably introduced and from time to time stimulated by a system of canvassing which is very unfair

to competing doctors; they are controlled by Workmen's Committees, which are not responsible bodies like the Insurance Committee: they are subject to little or no central control, they allow no direct representatives of the medical profession on them, nor are they guided, as the Insurance Committee largely is in medical matters, by a purely medical Committee—the Panel Committee. Experience has shown that the service provided is on the whole unsatisfactory as compared with that given by doctors under the normal system; most of these Schemes have disappeared after a comparatively short but unsatisfactory existence; and it is hoped that the Royal Commission will recommend such changes as will make it impossible to finance such Schemes out of National Health Insurance Funds.

### APPENDIX III.

#### OPHTHALMIC BENEFIT.

1. Among present "Additional benefits" dental and ophthalmic are easily first in demand and in value to insured persons.

2. Ophthalmic benefit appeals greatly to the insured person, for the symptoms of eye strain are most disturbing and are more frequent with the increasing complexity of modern life.

3. This benefit should be dealt with administratively in the way suggested in the main body of the memorandum with regard to the "treatment benefits" in general by being removed from the administration of Approved Societies. Under the present system, however, a few Approved Societies have made arrangements with specially qualified practitioners on behalf of their members and these arrangements are not open to the objection which is set out in the following paragraphs.

4. Other Approved Societies have entered into arrangements which are open to serious criticism and are certain to lead to grave danger to the insured persons.

5. These Societies have arranged for the provision of spectacles by opticians and without the necessary preliminary examination by a competent medical practitioner. The arrangement, it is alleged, is cheap. But cheap methods in dealing with human beings usually prove costly in the long run. It is sure to prove so in this regard, both immediately and in the future. An ophthalmic benefit secured through a competent medical practitioner is a full consultation covering external or internal diseases of the eye, refraction work, and vascular and neural examinations. The results of these examinations should be communicated to the insurance practitioner and would afford him information regarding his patients which he cannot get otherwise, and which will be a material guide to his work. The bare provision of spectacles by a "sight-testing" optician cannot secure these benefits, for he is not trained in the diseases of the eye and of the body which are concerned therewith. Apart from the risks inevitable in the employment of untrained or part-trained men for the examination of the most delicate sense organ and one closely connected with the brain, examinations by sight-testing opticians are inadequate and therefore unprofitable.

6. The utilisation of medical practitioners for this purpose will make it certain that within a very few years there will be a full supply of well-trained and competent ophthalmologists ready and able to do this work to the best advantage. If the employment of sight-testing opticians be continued or extended there will be a diminution of the supply of doctors willing to do this work, to the ultimate disadvantage of the community.

7. Further, as examination of the refraction of the eye for the purpose of fitting spectacles is regarded as a form of medical treatment, medical practitioners, with due regard to the disciplinary disabilities that would follow, or with proper regard for the welfare of their patients, cannot send their patients or be party to sending their patients to persons not on the *Medical Register*.

## British Medical Association.

### CURRENT NOTES.

#### Preparations for the Opening of the New House of the Association.

MEMBERS will be interested to learn that the alterations and decoration of the new house are progressing steadily. It is too early yet to be able to give any definite particulars as to the opening ceremony, but so far as can be seen the date will be either July 14th or 15th, and the ceremony will consist not only of the opening of the new house but the dedication of the memorial gates which are to be erected to commemorate the members of the Association who gave their lives in the great war. The Council in November last sent an invitation to all the Overseas Branches to make a special effort to be represented at the opening ceremony, as well as at the Annual Meeting at Bath, and many responses have already been received which show that a good gathering of our brethren from over the seas may be expected. We shall shortly be in a position to report further very agreeable indications of the interest in the great event which is being shown by the Dominions.

#### Life Insurance without Medical Examination.

The Medical Secretary not infrequently receives letters from members of the Association informing him that they have been asked to give information about the previous health of patients who have been accepted for life insurance without medical examination, and who have died shortly afterwards. His advice to them is invariably that they should not give any information without the written consent of the relatives of the deceased. It can hardly be doubted that the object of insurance companies in making such inquiries is the chance of getting information regarding the previous health of the deceased which may enable them to dispute the claim and thereby evade a financial liability which they have incurred, without taking the usual steps to protect themselves against undue risk. Whether a fee is offered or not is beside the point: the fact remains that the insurance company would seem to be looking to the doctor to pull the chestnuts out of the fire. The line which should be adopted by doctors in cases of this kind is to refuse information and to inform the relatives that they should tell the insurance company quite plainly

that if the claim is not settled promptly they will sue in the courts. This advice has been given to a number of correspondents, and it may be useful to make it more widely known.

#### South African Medical Congress, 1925.

At the invitation of the Natal Inland Branch of the British Medical Association, the twentieth South African Medical Congress will be held in Pietermaritzburg during the week beginning July 6th, under the presidency of Dr. D. Campbell Watt. Five sections have been arranged—namely, medicine and mental hygiene; surgery; public health; obstetrics and gynecology; and special subjects. Practitioners desirous of contributing papers are invited to communicate with the honorary general secretary of the Congress, Dr. C. G. Kay Sharp, Education Department, Pietermaritzburg. A circular will be sent to those indicating a desire to be present at the Congress, when the details of the arrangements have been decided. The membership fee is two guineas.

#### Salaries of Part-time Medical Officers of Health.

In January the Medical Secretary of the British Medical Association sent to all part-time medical officers a questionnaire asking for particulars in regard to their salaries. The object of this set of questions was to obtain a body of information which would enable the Medical Secretary to advise inquirers as to what was customary in similar appointments in various parts of the country. So far only about half of the officers addressed have sent answers. It is hoped that those who have not already replied will do so as soon as possible.

#### Trade Unions and Unqualified Practice.

The attraction that unqualified practice has always had for certain individuals is well known, but it is rather melancholy to find at this time of day a trade union actually providing for its members treatment by a well known "consumption cure." Not only has a branch of one trade union (the National Union of Boot and Shoe Operatives) provided and paid for the treatment, but in one case recently reported to us has put considerable pressure upon the member to dissuade him from discontinuing the treatment. In view of the strong remarks made by the Select Committee of the House of Commons on those who profess to "cure consumption" it seems a pity that the money of trade unionists should be wasted in this way.

## Association Notices.

### SPECIAL REPRESENTATIVE MEETING.

NOTICE is hereby given that a Special Representative Meeting of the Association will be held in the Wesleyan Central Hall, Westminster, London, on Thursday, March 12th, 1925, at 9.30 in the forenoon, on the requisition of the Council, to consider the following motion:

That the members of the Representative Body present be authorized to attend a Conference called for Thursday, March 12th, and (if necessary) Friday, March 13th, 1925, at 10 a.m., in association with representatives of Local Medical and Panel Committees, to consider a Memorandum of Evidence proposed to be submitted to the Royal Commission on National Health Insurance.

By order of the Chairman of the

Representative Body,  
ALFRED COX.

February 18th, 1925. Medical Secretary.

### TABLE OF DATES.

Mar. 16, Mon.	Branch Reports for 1924 due by this date.
Mar. 25, Wed.	Council.
Mar. 30, Mon.	Nomination papers available for election of 24 members of Council by grouped Home Branches, 2 Public Health members of Council, and 4 Representatives of Public Health Service in Representative Body.
April 11, Sat.	Annual Report of Council appears in SUPPLEMENT.
April 25, Sat.	Last day for receipt of nominations for election of 24 members of Council by grouped Home Branches, and of 2 Public Health members of Council, and 4 Public Health Service Representatives.
May 9, Sat.	Publication in SUPPLEMENT of nominations for election of 24 members of Council by grouped Home Branches, 2 Public Health members of Council, and 4 Public Health Service Representatives. Voting papers posted.
May 12, Tues.	Independent motions for A.R.M. Agenda must be received at Head Office by this date.
May 16, Sat.	Last day for receipt of voting papers for election of 24 members of Council by grouped Home Branches, 2 Public Health members of Council, and 4 Public Health Service members of Council.
May 20, Sat.	Publication in SUPPLEMENT of results of Council elections by grouped Branches, and of election of members of Council and Representatives in Representative Body by Public Health Service members.
June 4, Thurs.	Nomination papers available for election of 12 members of Council by grouped Home Representatives.
June 10, Wed.	Names of Representatives and Deputy-Representatives must be received by this date.
June 18, Thurs.	Council.
June 27, Sat.	Meetings of Constituencies must be held between this date and July 17th to instruct Representatives.
July 3, Fri.	Supplementary Report of Council appears in SUPPLEMENT. Amendments and riders for issue in A.R.M. Agenda must be received by this date.
July 17, Fri.	Annual Representative Meeting, Bath. Nominations for election of 12 members of Council by grouped Representatives must be received (at A.R.M., Bath) by this date.
July 18, Sat.	Annual Representative Meeting, Bath.
July 20, Mon.	Council, and Annual Representative Meeting, Bath.
July 21, Tues.	Annual Representative Meeting, Bath. Annual General Meeting, Bath, President's Address.
July 22, Wed.	Council Meetings of Sections, Conference of Honorary Secretaries, Bath.
July 23, Thurs.	Meetings of Sections, etc., Bath.
July 24, Fri.	Meetings of Sections, etc., Bath.

ALFRED COX, Medical Secretary.

### BRANCH AND DIVISION MEETINGS TO BE HELD.

**BIRMINGHAM BRANCH: COVENTRY DIVISION.**—A meeting of the Coventry Division will be held on Tuesday, March 3rd, at the Coventry and Warwickshire Hospital, at 8.30 p.m. Agenda: Correspondence; paper by Dr. Wright, pathologist, to the Coventry and Warwickshire Hospital.

**KENT BRANCH: DARTFORD DIVISION.**—A meeting of the Dartford Division will be held at the New Erith Hospital at 3 o'clock to-day (Friday, February 27th). Mr. H. S. Souttar, C.B.E., F.R.C.S., of the London Hospital, will give an address on modern treatment of fractures, and it is hoped that all practitioners in the Dartford area will be able to attend.

**EDINBURGH BRANCH.**—The winter clinical meeting of the Edinburgh Branch will be held in the Royal Infirmary, Edinburgh, to-day (Friday, February 27th). All members of the profession are cordially invited. Senior medical students desirous of attending will be admitted by card, obtainable from Mr. F. E. Jardine. The museum will be open from 10 a.m. to 6 p.m. Arrangements will be made for holding special clinics during the day. The clinical meeting will be held at 3.30 p.m. Dinner at 6.30 in the Caledonian Station Hotel (morning dress); dinner ticket, price 10s. 6d.

**LANCASHIRE AND CHESTER BRANCH: HYDE DIVISION.**—At a meeting of the Hyde Division to be held at the Hyde Town Hall on Thursday, March 12th, at 8.30 p.m., Dr. Ralphs will give his impressions of a short visit to the United States of America.

**METROPOLITAN COUNTIES BRANCH: CAMBERWELL DIVISION.**—A meeting of the Camberwell Division will be held at Bermondsey and Rotherhithe Hospital, Lower Road, Rotherhithe, on Wednesday, March 4th, at 9 p.m., when Dr. N. Mutch, assistant physician, Guy's Hospital, will give an address on rheumatoid arthritis.

**METROPOLITAN COUNTIES BRANCH: CITY DIVISION.**—A meeting of the City Division will be held at the Metropolitan Hospital, Kingsland Road, on Tuesday, March 10th, at 9.30 p.m., when Sir H. E. Bruce-Porter will read a paper on medical practice and its pitfalls.

**METROPOLITAN COUNTIES BRANCH: SOUTH-WEST ESSEX DIVISION.**—A meeting of the South-West Essex Division will be held at the Woodford Jubilee Hospital, Woodford Green, on Tuesday, March 3rd, at 3.30 p.m. After the termination of the ordinary business a paper will be read at 4.15 p.m. by Mr. C. H. S. Frankan, C.B.E., F.R.C.S., on tuberculous glands of the neck. Tea at 3.15 p.m.

**MIDLAND BRANCH: CHESTERFIELD DIVISION.**—At the meeting of the Chesterfield Division, to be held at the Maternity Hospital, Chesterfield, on Friday, March 13th, Dr. A. J. Hall, professor of medicine, University of Sheffield, will give an address on "Diagnostic Bunkers."

**SOUTHERN BRANCH: WINCHESTER DIVISION.**—A meeting of the Winchester Division will be held at 4, The Square, Winchester, on Thursday, March 19th, at 3.30 p.m., when a British Medical Association Lecture will be given by Professor H. Maclean on the present position of endocrine diseases from a clinical standpoint.

**STAFFORDSHIRE BRANCH.**—The second general meeting of the session will be held at the Stork Hotel, Walsall, on Thursday, March 5th; the President, Dr. J. W. Dawes, will take the chair at 4 p.m. Business: Correspondence. Exhibition of cases. Papers:—Dr. S. C. Dyke: The Differential Diagnosis of Glycosuria; Dr. G. F. Hayeraft: A New Aspect of Herpes Ophthalmicus; Dr. F. G. Layton: Concerning Doctors. Exhibitions of pathological specimens, etc. Dinner at 6.15 p.m. at the Stork Hotel, Walsall. Members proposing to attend are requested to notify the honorary general secretary, Dr. W. Webster, by March 2nd.

**SURREY BRANCH: GUILDFORD DIVISION.**—At the meeting of the Guildford Division, to be held at the Royal Surrey County Hospital, Guildford, on Thursday, March 5th, Sir Crisp English, K.C.M.G., will open a discussion on abdominal pain.

**YORKSHIRE BRANCH: WAKEFIELD, PONTEFRAC, AND CASTLEFORD DIVISION.**—At the meeting of the Wakefield, Pontefract, and Castleford Division, to be held at the Bull Restaurant, Wakefield, on Thursday, March 12th, Mr. E. W. Bain, F.R.C.S. (Leeds), will give a lecture on middle-car supposition.

## Meetings of Branches and Divisions.

### METROPOLITAN COUNTIES BRANCH: WESTMINSTER AND HOLBORN DIVISION.

#### The Relationship between Doctor and Patient: Some Legal Aspects.

A DINNER MEETING of the Westminster and Holborn Division was held at the Criterion Restaurant, under the chairmanship of Dr. HOWARD HUMPHRIS, on February 19th.

Mr. OSWALD A. HEMPSON, solicitor to the Medical Defence Union, gave an address on some of the legal aspects of the relationship of doctor and patient. This relationship was one of contract—on the doctor's side to exercise reasonable care and skill and to do his utmost to effect a cure, and on the patient's side to pay reasonable fees. No guarantee of correct diagnosis or certain cure was involved in the contract; attempts had been made to infer such a guarantee, but this had never been confirmed by law. The expected skill varied with the individual practitioner. From one who held himself out to be an expert and accepted fees under that title greater skill would be required than from the ordinary general practitioner. Care, on the other hand, was a constant factor. Cases frequently came to the Medical Defence Union in which the doctor stated that he had advised the patient to follow a certain course of treatment or allow a consultant to be brought in, and the patient had refused. It was very important that the medical man should obtain and preserve written evidence of that advice and refusal. He should repeat the advice in the form of a letter to the patient and retain a copy. It had been suggested that patients should be got to sign an indemnity, but the speaker did not believe that that would carry any real protection; it would not absolve the practitioner from exercising a reasonable degree of care and skill, and if it was decided that there had been dereliction induced by the fact that the practitioner had protected himself beforehand by the indemnity, the damages awarded against him might be correspondingly heavy. It was necessary also to remember that the practitioner was responsible for the acts of others, such as those of a partner within the business of the partnership, or of an assistant within the terms of his employment. In the famous case known as the St. Bartholomew's Hospital case it was laid down that the surgeon was responsible for all that happened in the operating room after the door was closed; but recently a different view had been taken in a South African court, where, in an action against a surgeon for allowing a swab to remain in the body of the patient, the judge had held that the surgeon could not be held liable because, by custom, there had been delegated to the nurse the duty of checking the swabs, and it could not be to the interest of the patient that the surgeon himself should undertake this duty. To establish criminal negligence it was necessary to prove something far more serious than such negligence as would entitle a patient to civil damages. He directed attention to the report

in the BRITISH MEDICAL JOURNAL of recent proceedings, and particularly to the dictum of Mr. Justice Stephen on manslaughter by negligence which was frequently quoted in those proceedings (February 7th, p. 286). In a criminal case it was care rather than skill which was the determining factor.

Often it was imperative for a medical man to make some communication with regard to the condition or health of a patient, and that brought him into the sphere of possible action for slander or libel. In slander, because it was a transitory thing (save in four cases which were treated as being actionable *per se*) it was necessary to prove, not only that the slander had been spoken, but that actual damage had resulted; in libel, which had a more permanent character, it was not necessary to prove special damage. There were various lines of defence to such actions. The defence of justification, that what was spoken was true in substance and fact, was dangerous because, if the verdict should go against the defendant, the offence was aggravated and the damages increased. The defence of fair comment on a matter of public interest hardly arose in ordinary professional relations. The defence of qualified privilege was most frequent, and within this category came consultations between medical men, statements made by a medical man to the relatives of the patient, and statements made in discharge of a legal, moral, or social duty. But it must not be forgotten that this defence of qualified privilege could be rebutted by what the law called malice, which had a wider interpretation than malice in ordinary speech, and was held to include any corrupt or wrong motive or spite or ill will, or, in other words, any indirect motive other than a sense of duty. The making of statements which were known to be false, or statements which were made recklessly, without care whether they were true or false, would be clear proof of malice. In giving certificates it was clearly necessary to speak only of facts actually discovered by the certifier as the result of his examination, and not to make my statement as to what might have been the condition at some antecedent date, or if such statements as the latter were put in, it must be clearly stated in the certificate that they were purely surmise. He was aware that the Harnett case had caused many scratchings of heart, but, that case notwithstanding, the Act of 1890 still governed the situation, and this gave the medical profession a substantial protection. At an early stage in any proceedings arising out of anything done in pursuance of the Lunacy Act a medical man could apply to the court for the dismissal of such proceedings, and the judge, on being satisfied that there was no reasonable ground for alleging want of good faith or reasonable care, could direct the proceedings to be dismissed. The Act of 1890, indeed, gave a greater protection than the common law, because there was no mention in that Act of skill, but only of reasonable care and good faith, which latter might be defined as acting with no ulterior motive, the only guiding factor being the interest of the patient. His own opinion was that the profession need not fear that the Harnett case had added to its responsibilities. The same law remained to be applied, there was the same necessity to consider the individual facts of every case, and, provided the doctor acted with reasonable care and good faith, he had absolute protection under the Act.

It had often been suggested (Mr. Hempsen continued) that members of the profession should act as informers to the police, but medical men had rightly shown themselves disinclined to serve as private detectives. If a liability of that sort were to be admitted it would, in many cases, be a great abuse of the trust which those in physical or mental trouble reposed in the members of the profession. He recalled being present, some years ago, at a meeting between the Law Officers of the Crown and representatives of the medical profession when this question was discussed. At that meeting all that the Lord Chief Justice of the time asked of the profession was that in cases where there was good reason to believe that an illegal operation had been performed by some outside party a doctor should inform the police, and Mr. Hempsen thought that even in making this modified request the Law Officers realized that they could not enforce such an obligation. That was really a great tribute to the confidence existing between doctor and patient. He concluded by saying that if the profession had many obligations it had also certain privileges. The practice of medicine by unqualified persons in this country was not prohibited, but certain disabilities were attached to such practice, and an unqualified practitioner was not able to sustain an action for the recovery of fees. To the medical profession was accorded the right to sign certain formal certificates. The opinion of the doctor was accepted in many courts, and a certificate from him had a considerable influence upon a case. Members of the profession alone were entitled to hold certain offices, they were exempt from jury service and from training for the militia, a certain latitude was allowed to them when exceeding the speed limit on the highway, and another odd privilege was that their horses were not at law allowed to be harnessed to the local fire engine!

A discussion took place, in which Dr. WILLIAM HILL, Dr. PORTER PHILLIPS, Dr. GILBERT SCOTT, and others took part, and some interesting (though not always reportable!) medico-legal experiences were exchanged.

#### EDINBURGH BRANCH: SOUTH-EASTERN COUNTIES DIVISION.

A MEETING of the South-Eastern Counties Division was held on February 11th in the Railway Hotel, Newtown St. Boswells, when Dr. C. J. W. DIXON was in the chair.

Sir ROBERT PHILIP gave a most interesting address on tubercularization and detubercularization, and arranged for a demonstration of the effects of a tuberculosis infection in guinea-pigs which showed very well the spread of the infection through the lymphatics from one group of glands to another, at first unilaterally but finally bilaterally, and involving organs such as the spleen, liver, and lungs. He pointed out (1) that these were definite focal effects arising from infection at a primary focus, the infection travelling in a definite path from one group of glands to another; (2) that in addition there were also systemic effects such as loss of weight and appetite, and rise of temperature. As a result of the route travelled by the tubercle bacilli he deduced that in the diagnosis of tuberculosis very careful attention should be paid to the lymphatic system.

Sir Robert Philip laid down two broad propositions: (1) that tubercularization—not tuberculosis—was practically universal in civilized countries; (2) that the infection of tuberculosis was for the most part effected in childhood. In view of these propositions he suggested that great attention should be paid to children, and particularly to delicate children, who should be reviewed from time to time with a view to determining the extent of tubercularization. With regard to such children, he said that environmental influences and such diseases as measles and whooping-cough, while not in themselves being the cause of tuberculosis, lowered the bodily resistance to such an extent that they might foster the development of the process.

With regard to detubercularization, Sir Robert Philip was very emphatic that detubercularization should not be delayed until the gross manifestations appeared, and emphasized the fact that surgical procedures for tuberculosis were at the best "local toiletting," and that they did not affect retubercularization. He personally recommended the innunction of tuberculin ointment—1 to 50 per cent.—once a week as a routine procedure; and by the kindness of Dr. Page a number of tuberculous cases were shown in which great improvement had been effected by this treatment.

On the motion of Dr. OLIVER a very warm vote of thanks was accorded to the lecturer.

#### LANCASHIRE AND CHESHIRE BRANCH: BLACKPOOL DIVISION.

A GENERAL meeting of the Blackpool Division was held at the Victoria Hospital, Blackpool, on February 11th, when Dr. STEWART was in the chair. After the members had been entertained to tea by the matron of the hospital, an instructive demonstration of clinical cases, skiagrams, and pathological specimens was given by Drs. HODGSON, BAIRD, ENGLISH, and DEVERS. The demonstration covered a very wide field—medical, surgical, obstetrical, and pathological.

On the motion of Dr. STEWART, seconded by Dr. CORRI, the best thanks of the meeting were unanimously accorded to Drs. Hodgson, Baird, English, and Devers.

It was announced that provisional arrangements were in hand for a meeting of the Division on March 18th, when the coroner had promised to give an address.

#### METROPOLITAN COUNTIES BRANCH: CITY DIVISION.

MEETINGS of the City Division were held respectively on January 13th and February 10th, both at the Metropolitan Hospital. On January 13th, when forty-two members were present, Mr. W. McADAM ECCLES, M.S., F.R.C.S., read a paper, illustrated by lantern slides, on the lessons learnt from the x-ray plates taken during 1924 at St. Bartholomew's Hospital. There was a most interested audience. Mr. McAdam Eccles was unanimously thanked for his very instructive lecture, and also for having plates specially prepared for this demonstration.

The meeting on February 10th was also attended largely, fifty-four members being present. Dr. EDWIN SMITH, coroner for North-east London and lecturer on medical jurisprudence at St. Thomas's Hospital, read a paper on some legal relationships of the practitioner, with special reference to the coroner's court. The audience was deeply interested, and a hearty vote of thanks was accorded to the lecturer.

Prior to Dr. Edwin Smith's paper the following resolution, moved by Dr. C. E. EVANS and seconded by Mr. H. VAUGHAN PRICE, F.R.C.S., was carried without dissent:

That this Division views with ever-increasing alarm the constant encroachments and threats of further encroachments on private practice, not only by the agents of the Ministry of Health (National Health Insurance Acts) and municipal bodies in infant welfare work, school treatment, and clinics, tuberculosis persons, without any obvious increased benefit to the public, but also by the Medical Association which state what steps are being taken to guard the interests of the profession generally.

## METROPOLITAN COUNTIES BRANCH: SOUTH MIDDLESEX DIVISION.

An ordinary meeting of the South Middlesex Division was held at St. John's Hospital, Twickenham, on January 21st, when, in the absence of Dr. G. S. Ewen (Chairman), Dr. GÜNTHER presided.

Dr. Günther opened a discussion on scarlet fever from a public health point of view. He stated that the population of Hampton Wick was 2,417, and had not varied much since 1893, during which period 145 cases of scarlet fever had been notified, resulting in two deaths. This gave an average of about four cases a year. There were no facilities for isolation hospital accommodation until 1906, and for some years advantage was only taken sparingly of such facilities. From a public health point of view the management of this disease often presented points of difficulty, especially in view of the fact that in the vast majority of cases the disease was a mild one. Very little was known about the etiology of the disease. They were told that the organism was a haemolytic streptococcus, but there must be factors at work which at certain times caused numerous children to contract the disease. In some years the complaint was highly infectious and in other years only slightly infectious. One thing was certain—that until the bacillus was isolated very little advance in the control of the disease could be attained. Dr. Günther said that diagnosis often presented great difficulties, but no doubt in future years might be remedied, as the writings of George and Gladys Dick in America seemed to show. In certain cases, owing to difficulties in diagnosis, the general practitioner and the medical officer of health were not infrequently placed in a dilemma. Dr. Günther was of the opinion that scarlet fever and German measles were often taken one for the other. Having no isolation hospital in the district, most of the cases were sent, under arrangement, to certain other fever hospitals, but the remainder had to be treated at home.

A hearty vote of thanks was accorded to Dr. Günther for his interesting communication.

## METROPOLITAN COUNTIES BRANCH: WILLESDEN DIVISION.

At the Comedy Restaurant, on Sunday evening, February 15th, Dr. WOOLLEY STOKER presided over the first dinner of the Division. Dr. LOCK said the Burns Grace. In replying to the toast of the Division, proposed by Mr. F. D. SATER, surgeon to the Willesden General Hospital, the CHAIRMAN traced the history of the Division, which sprang from Hampstead in 1912, and after the Insurance Act lapsed and was attached to Harrow. Since its resurrection in 1919 it had prospered and the membership had doubled.

Dr. G. C. ANDERSON, Deputy Medical Secretary, British Medical Association, proposed the toast of "The hospitals in Willesden." Mr. G. FURNESS, chairman of the Willesden General Hospital, replying for his own and for St. Andrew's Hospital, Dollis Hill, expressed his pleasure at being present and being associated with the doctors. Dr. F. G. BUCHAN, for the Municipal Hospital, put in a plea for co-ordination of work and for preventive medicine. Dr. THAXER, of the Park Royal Hospital under the board of guardians, referred to the development of the surgical work in Poor Law hospitals. Proposing the toast of "The Ladies and the Guests," Dr. STURRIDGE emphasized the great work done by Mr. Furness in developing the Willesden General Hospital. Miss LAWRENCE, Intelligence Officer, British Medical Association, effectively replied, and Mr. JAMES JOHNSTONE, barrister, secretary of the Middlesex Panel Committee, welcomed the opportunity of showing the doctors that he was not merely a silent recorder of their opinions. Mrs. LOCK made a collection on behalf of the proposed maternity ward for the General Hospital and expressed satisfaction at the result. Dr. PATTERSON, before proposing the health of the Chairman, congratulated Drs. Lock and Sturridge on the excellence of the arrangements. He also referred to each of the nine preceding chairmen, and especially to the oldest, Dr. Macevoy, who was present, and was always consulted in cases of difficulty. Dr. STOKER's reply brought an enjoyable evening to a close.

## Correspondence.

## Insurance Remuneration.

SIR,—For the year 1924 practitioners in the Glasgow area have received a capitation rate of 8s., and we are told that no additional grant may be expected whereby our remuneration will be made up to the 9s. per caput which most of us understood the British Medical Association had obtained at the recent negotiations. During these negotiations the vast majority of us signed "strike notices" because we would not accept a capitation rate of 8s. 6d. Now it appears we have worked for a year for 8s., and next year may have to work for less. I would be interested to know if statistics are available giving the rate of remuneration received by practitioners in other areas, and whether, if our unfortunate plight in Glasgow is paralleled elsewhere, the British Medical Association can do anything to obtain for us the capitation rate which we were promised and awarded—that is, 9s.

Much capital was made by the Ministry of Health that panel practice meant a sure income and a complete freedom from bad debts. During 1923 the bad debts from my private practice amounted to 15 per cent., some of which I still hope to recover through a debt collector. During 1924 bad debts from my

panel practice amounted to 12½ per cent., all of which is irrecoverable.

Comment seems unnecessary.—I am, etc.,

Govan, Feb. 5th.

IAN D. GRANT.

\*\* We have referred this letter to the Scottish Medical Secretary, who writes as follows:

Dr. Grant's letter proceeds on a not uncommon misunderstanding as to the exact nature of the arrangements for payment under the insurance system which the profession has accepted. Some doctors have come into the service since the date when the general principles were agreed to, and others have forgotten what these were. It may be well to restate them now.

A capitation fee of 9s. does not mean a payment of 9s. for every person on a doctor's list at a particular time, since all the lists contain the names of persons who are dead or otherwise not entitled to medical benefit.

The total number of persons entitled to treatment for a given year is calculated by the actuary, and 9s. in respect of each of them is paid into the central pool. This sum forms the insurance premium. The insurance risk which the doctors carry is the risk of having to attend all those entitled to treatment. The insurance risk in each area is generally proportionate to the numbers on index registers, and the pool is divided amongst Insurance Committees pro rata to the index registers after adjustment for such things as temporary residents.

The insurance risk which each individual practitioner carries is again generally proportionate to the number of persons on his list, and the local pool is distributed in that proportion in all areas except those where the doctors prefer to be paid in proportion to the services which they render.

As the numbers on index registers and also the numbers on doctors' lists are in excess of the calculated total of persons entitled to benefit, the sum received obviously falls below 8s. per caput. The rate of inflation is believed to be uniform, but the proportion of persons on the index registers who have come on to doctors' lists varies among areas, which results in a variation in the sum received per caput. If two areas have the same total index register, the sum received by the two areas would be the same in each case; but if, say, 70 per cent. of the register have chosen a doctor in one area and 80 per cent. in the other, the sum per head of doctors' lists would be greater in the former case than in the latter, although the total sum received by the doctors would be the same in both areas.

The method of distribution is not ideal, but so far no better workable scheme has been devised.

## The Expansion of the National Health Insurance Medical Service.

SIR,—The above is what the "taking in of the dependants of insured persons" means. Now is the time to consider if the service is developing upon right lines.

To my mind there is one fatal flaw in the present system—that is, the autocratic bureaucratic government from the Ministry of Health. I believe the nation is instinctively correct in its hatred of bureaucratic government. If socialism and nationalization inevitably mean bureaucratic government, then they are damnable, and to be resisted by every intelligent citizen. But need this be so? Democratic socialism alone would be tolerable to an educated people.

Syndicalism—that is, the control of an industry by owners and workpeople, regardless of the communal interest—is as bad as the present capitalist system. Therefore the medical profession cannot, in justice, ask to control a national health system. That is what some doctors are thoughtlessly demanding.

I believe that the solution of these problems lies in claiming that an industry or a health service shall be controlled by a triple alliance of owners, workpeople, and representatives of the general community. Now let us try and apply this to the national health service. Governance by the Ministry of Health and its whole-time officials is every day becoming more tyrannical and objectionable. Before the profession agrees to extend further the area of service, thereby diminishing the area of general practice, let it insist upon the Whitehall governing body being radically altered.

The great merit of the Insurance Committees was that they represented insured persons, the doctors, and the general community. In like manner the Whitehall governing body must fairly and justly represent the same interests, and unless this be done I hope the joint meeting in London will refuse absolutely to have anything to do with an extension of the service. Two demands should be made:

(1) The Central Governing Committee should consist of representatives of insured persons, selected members of our

Insurance Acts Committee, and members of Parliament representing the community, with the Minister of Health as chairman.

(2) Regional medical officers shall be chosen by the panel doctors in the respective regions. Otherwise the medical profession is only providing more patronage for the party in power.

Now is the time to take the definite stand.—I am, etc.,

Southend-on-Sea, Feb. 17th.

FERDINAND REES.

#### *Royal Commission on National Insurance.*

Sir,—I recently drew attention (as it affects whole-time medical officers) to the proposed evidence to be submitted by the British Medical Association. May I now refer to it as it affects the people most concerned—the dependants of insured persons, to whom it is proposed to extend medical benefit? These dependants will include nearly all the school children of the country, and it is these that I wish to consider.

My excuse for venturing to discuss the question at all is that, as tuberculosis officer, I have some knowledge of the practices of all the general practitioners in the county, and, being on the staff of the county medical officer of health, I am closely associated with the school medical service. Also, having been in the county since 1903, I am able to compare conditions before and after the Insurance Act came into being.

The result of my experience is that I am sure that medical benefit has been of great value to the insured person, and I am all in favour of extending the Act to include their dependants. But I am very doubtful if the school children will benefit if, at the same time that they are given general practitioner treatment, they are deprived of all the existing forms of treatment provided by the school medical service.

Excluding treatment of eyes, teeth, tonsils, and adenoids, orthopaedics, and mental deficiency—all of which are admitted to require specialist treatment—the remaining defects treated by the school medical service are scabies, impetigo, ringworm, and pediculosis. Does the general practitioner want to treat these four ailments? And if so, what capitation fee would adequately remunerate him for the time and trouble needed? Extension of benefit to dependants is bound to be expensive, as they earn no wages and have no employers, so that all the cost must be borne by the State—that is, the taxpayer. It is therefore important that the capitation fee should be moderate.

I would suggest that if medical benefit is extended to dependants it should consist of general practitioner treatment, which would be in addition to, not in place of, existing forms of treatment supplied by local authorities.

Such a modified extension of medical benefit—

1. Would increase the amount of treatment given to children.
2. Would relieve the general practitioner from treating troublesome and comparatively trivial ailments.
3. Would exempt the general practitioner from keeping the necessary records, returns, and reports required by the Board of Education.
4. Would be less expensive than the British Medical Association scheme.
5. And lastly, it would provide for all the children the fatherly care of the family physician, which is so much to be desired, but is not necessary for the successful discovery of nits in a school child's head.

—I am, etc.,

Winsley, Wilts, Feb. 16th.

LEONARD CROSSLEY, M.D.

#### *The Record Card in Rural Practice.*

Sir,—I was delighted with "Kathleen Willie-Clarke-Hall's" doctor's racy description of his difficulties with his Record Cards (SUPPLEMENT, February 14th, p. 62). His case is a somewhat extreme one, though it could probably be capped by many a Welsh panel practitioner; still he speaks for us all. And the great moral deducible is, of course, the tragic waste of the doctor's time. Three or four minutes to find a single card, or to prove that one does not possess it, is too long to waste over a single patient during a strenuous hour and a half of "surgery," with anything from ten to thirty or more other patients waiting to have their ears found and to be then themselves examined and prescribed for and given their certificates.

At a busy time of year—often the whole time from October to May—a single-handed semi-rural practitioner such as I am will almost certainly have three or four serious cases on hand that he is anxious to get to see as early as possible. One of these cases may be three or four miles away in one direction, another equally as far in the opposite direction, and so on.

Starting a "surgery" at 9 a.m. one has, if possible, to be away on one's morning rounds by 10.30. "Doing the Record Cards" then would easily protract this consultation period by an entire hour. Similarly at the evening "surgery," which,

starting at, say, 6 p.m., goes on to 7.30 or 8 o'clock. If the Record Cards for the patients visited during the day and for patients who have consulted during the evening surgery hour have now to be tackled, there is work provided which will last till 9.30. But 9.30 is too late to be setting off on an evening round to the serious cases, who may again be miles apart—north, south, east, or west.

*Record keeping properly done is a manifest impossibility in practices of a certain type.* This is a cardinal point, which should long ago have been recognized by the bureaucrats.

A county M.O.H., or other county health administrator, comes down to his comfortable offices at 9 a.m., or later, to his clerks, lady typists, and all the amenities and comforts; at midday he can go out for an hour and a half to his lunch, and can retire from his day's work at whatever hour he likes in the afternoon. "A little record keeping" is quite a simple thing, he reflects, as he toasts his toes at his drawing-room fire before going off to an undisturbed night's rest. Now the county M.O.H. or other bureaucrat is not a fool; he is an able man for a practical certainty, and usually also a very tactful and charming man. But he is often lacking in one thing, and that is imagination. While toasting his toes at 11 p.m. he does not realize that the average general practitioner doing panel work may quite likely have started the day's work by having been "out at a confinement" all the previous night, and that often that same general practitioner is hauled out of bed for a longer or shorter period three or four nights running. He does not realize that that general practitioner after three or four hours' sleep tackles his morning "surgery" (four-fifths of which is probably for trifling ailments), feverishly impatient to get through it quickly in order to get away to a case of possible intestinal obstruction four or five miles away, or to a case of pneumonia with a shaky heart. He does not realize that this same general practitioner (who ought, according to Memo. 274/1.C., to be cheerfully carrying out his "obligation" to keep records), with these yesterday's serious cases worrying him, has probably received during surgery hour several messages by note or telephone or telegram to "please come at once" to various other fresh cases at varied points of the compass, one of which may be a confinement call and another a summons to a serious accident. He does not, I repeat, attempt to realize or visualize what goes on day after day in the busy doctor's practice. With real urgency in half a dozen different directions all pulling at the doctor simultaneously, what time can possibly be given to fiddling about with Record Cards at all?

Whether the Record Cards under any circumstances are of much real use is extremely doubtful. Four years ago an expression of opinion, hailing from workers with the late Sir James Mackenzie at St. Andrews, seems to me to be conclusive. I quote the final paragraph of their statement as it appeared in the *Times* of January 12th, 1921:

"The only function of the insurance cards that can to our minds be of any value is that the notes afford proof that the patient was incapacitated and therefore entitled to benefit. And until the whole subject of non-terminal affections has been worked out in such institutions as ours, in limited areas, as you suggested, any attempt of the Ministry of Health to obtain statistics of value is folly."

The medical correspondent of the *Times*, in sending this "considered opinion"—for such it appears to me to be—to his paper, makes this devastating remark:

"In no area has medical recording received so much careful attention as at St. Andrews, where the special investigation into the earliest sign of disease is being carried out under the direction of Sir James Mackenzie."

But supposing that the medical advisers of the Ministry of Health were right and Sir James Mackenzie and his associates were wrong, and that the Record Cards are of value: then I submit—

1. That they are of real value only when ideally kept.
2. That they cannot possibly be ideally kept in very many types of practice; and in such types of practice—
3. That the attempt to keep them is a heart-break to a conscientious practitioner, a waste of valuable time, and an act of utter folly.
4. That they can only be carefully kept (a) by the right type of doctor in a selected type of practice; (b) by such a number (comparatively small) of men as will produce a not unmanageable amount of material.

Kathleen Willie-Clarke-Hall's doctor offers two solutions of the problems of the Record Card and its keeping by the panel practitioner:

1. That the patient keep his Record Card himself and produce it when claiming advice.
2. That the Record Card be abolished.

May I suggest an additional alternative—namely:

3. That the present system of Record Cards be acknowledged by the Ministry of Health to have failed of its object. That a new simple Record Card be given to, and kept, by each panel patient, and produced by him to his doctor on one or two occasions during any illness. On this could be entered any salient

feature likely to be of use to his present or any future doctor as memorandum or as guide.

That Record Cards, as elaborate as may be, be issued to a certain number of medical men on the panel who might undertake their keeping for any of the following or similar reasons: (a) That the number of their panel patients is comparatively few. (b) That their conditions of working are favourable (the existence of partners, assistant, book-keeper, etc.). (c) That they have a natural aptitude or liking for statistics.

That a levy of 1d., or other agreed figure, per head of the patients on the non-record keeping practitioners' lists be made, and that the resulting sum be pooled and divided out amongst these record-keeping practitioners.

On some such lines, Sir, I think that a way might be made for us out of our troubles. If the present Ministry of Health would look into the possibilities of some such scheme, and act upon their findings, and if they would at the same time review the whole question of certification (99 per cent. of so-called "lax certification" is merely ordinary justice to the insured person meted out to him by a conscientious fact-knowing member of a honourable, State-recognized profession) the "teething" difficulties of the National Health Insurance scheme would practically be a thing of the past, and 99 per cent. of the medical men who are now trying honestly to fulfil their obligation to the State would breathe a purer air. —I am, etc.,

February 17th.

A NORTHERN PRACTITIONER.

## Naval and Military Appointments.

### ROYAL NAVAL MEDICAL SERVICE.

SURGEON CAPTAIN H. J. CHATER to the *Tamar*, additional, and to *Tamar* additional for R.N. Hospital, Hong-Kong from date of joining.

Surgeon " " the *Egmont*, additional, and to the *Egmont*.  
Sergeant " " T. Wylie and L. F. Strugnell to the *Atreco*; A. G. McKee to the *Verdon*, temporary; P. J. Inman to the *Titanic*; R. P. Nimmo to the *Calyppo*; A. G. Anderson to R.N. Hospital, Simonstown; G. E. Heath to the *Thunderer*, temporary; J. A. Watson, appointment to the *President*, additional for five months' course cancelled; E. R. Kelley and A. W. Gunn to the *Egmont*, additional, and to the *Egmont* for R.N. Hospital, Malta; H. F. Stephen to the *Centurion*.

Surgeon Lieutenant E. C. Davis to the *Stuart*.  
Surgeon Lieutenants (short service) M. B. Devane transferred to permanent list, and J. E. Clark transferred to permanent list as Surgeon Lieutenant Commander.

Mr. R. M. L. Hall has entered as Surgeon Lieutenant and appointed to R.N. Hospital, Haslar, for course.

### ROYAL NAVAL VOLUNTEER RESERVE.

W. E. M. Wardill entered as Surgeon Lieutenant and attached to Tyne Division.

### ROYAL ARMY MEDICAL CORPS.

Lieut.-Colonel J. Dorgan retires on retired pay.  
The following Captains to be Majors: H. N. Sealy, A. Jackson (prov.), E. C. Beddows, M.C., J. Rowe, M.C. (prov.), W. P. Croker (prov.), A. B. H. Bridges, O.B.E., A. G. Brown (prov.), R. Hemphill, D.S.O.  
Captain T. Parr and Lieutenant T. W. Davidson are seconded for duty with the Sudan Defence Force.  
Lieutenant (on probation) M. A. Graham-Yooll resigns his commission.

### ROYAL AIR FORCE MEDICAL SERVICE.

Flight Lieutenant A. Briscoe to R.A.F. Central Hospital, Finchley.  
Flying Officers G. J. Hanley to R.A.F. Depot; F. L. White to No. 1 Flying Training School, Netheravon; G. J. Griffiths to Research Laboratory and Medical Officers' School of Instruction, Hampstead, on appointment to a short-service commission for short course; C. G. J. Nicholls and B. Pollard to R.A.F. Depot.

### REGULAR ARMY RESERVE OF OFFICERS.

#### ROYAL ARMY MEDICAL CORPS.

Major S. W. Sweetnam, having attained the age limit of liability to recall, ceases to belong to the Reserve of Officers.

### INDIAN MEDICAL SERVICE.

Lieut.-Colonel J. B. D. Hunter, O.B.E., is granted leave on average pay for seven months.  
Lieut.-Colonel " " Rules, from October 20th, 1924.  
Lieut.-Colonel " " Officiating Public Health Commissioner confirmed in the appointment, with effect from " " Civil Surgeon, Simla West, is granted leave on average pay for five months and nineteen days, with effect from October 8th, 1924.  
Captain (now Major) G. F. Graham to be acting Lieut.-Colonel while commanding a Field Ambulance in East Africa, from April 16th, 1917, to November 2nd, 1917.  
Major A. E. Griseewood has retired from the service.  
Captain A. L. Watts has resigned the service.

### TERRITORIAL ARMY.

#### ROYAL ARMY MEDICAL CORPS.

Colonel T. Kay, D.S.O., T.D. (late R.A.M.C., T.A.), to be Colonel and Assistant Director of Medical Services 52nd (Lowland) Division, T.A., vice Colonel G. H. Edlington, T.D., R.H.F., who vacates on completion of tenure of appointment.

Lieut.-Colonel (Brevet Colonel) F. Whallier, D.S.O., T.D., from R.A.M.C., T.A., to be Colonel, with precedence as from February 16th, 1924, and Assistant Director of Medical Services 48th (West Riding) Division, T.A., vice Colonel A. D. Sharp, C.B., C.M.G., T.D., R.H.S., who vacates on completion of tenure of appointment.

Major T. A. Hindmarsh to be Lieutenant-Colonel and to command 50th (1st Northern) Casualty Clearing Station.  
Lieutenant D. Ross to be Captain.

To be Lieutenants: Lieutenant N. G. Hill, M.C. (late Duke of Lancaster's Own Yeomanry); Second Lieutenant W. S. C. Copeman (late 1st Reserve); Second Lieutenant S. Vatcher

Colonel.  
Colonel D. J. Graham, O.R.E., to be Brevet

Superintendence for Service with the O.T.C.—Captain A. Fowler (late R.A.M.C., S.R.) to be Captain, with precedence as from February 8th, 1917, for service with the Medical Unit, Aberdeen University Contingent, Officers' Training Corps.

### COLONIAL MEDICAL SERVICES.

Dr. J. O. Shireore, Deputy Principal Medical Officer, appointed Principal Medical Officer, Tanganyika. Dr. A. J. Borg appointed District M.O. and M.O.H. Labasa, Fiji. Dr. T. Clunie appointed District M.O. and M.O.H. Levuka, and M.O.H. Olanai, Fiji. Dr. V. W. T. McGusty appointed District M.O. and M.O.H. Lautoka, Fiji. Dr. R. J. Colbert appointed M.O. Federated Malay States. Dr. R. H. Miller, M.O. Gambia, transferred to Nigeria. Dr. C. B. Jennings appointed M.O. West African Medical Staff, Sierra Leone. Dr. H. G. Willshire appointed M.O. Nyasaland, on probation. Dr. W. J. McClintock is confirmed in his appointment of M.O. Nigeria. Drs. W. Milne-Tough and R. Bury, Nyasaland, have relinquished their duties of Senior and Principal Medical Officer

McNaughton transferred from Tabora to be of Venereal Disease, Bukota District. Dr. J. H. From Tanga to Moshi, Tanganyika. Dr. J. M. (ant M.O.H.) Nairobi Municipal Area, Eastleigh, Township Area, Nairobi and Kyambu Districts, appointed M.O. in charge Uganda Railway Con- Dr. P. H. Rawson, M.C., has resigned his appointment as M.O. Uganda.

## VACANCIES.

BARNET: WELLHOUSE HOSPITAL—Assistant Resident Medical Officer. Salary £150 per annum.

BIRMINGHAM: GENERAL HOSPITAL—Medical Registrar and Resident Medical Officer. Salary £155 per annum.

CAMBRIDGE: ADDENBROOKE'S HOSPITAL—House-Surgeon (male). Salary at the rate of £130 per annum.

CHILDREN'S HOSPITAL, Balmain Street, E.13.—Honorary Physician.

DERBYSHIRE COUNTY COUNCIL—County Medical Officer of Health. Salary £1,400 per annum.

ELING BOROUGHS—Assistant Medical Officer of Health. Salary £600 per annum.

FEDERATED MALAY STATES.—Research Studentship in Tropical Medicine. Salary 500 dollars a month (£700 a year).

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Surgical Registrar. Salary £200 per annum.

ILLIUM DISPENSARY.—Honorary Surgeon.

INVERNESS: NORTHERN INFIRMARY—Junior Medical Resident (male, unmarried). Salary £100 per annum.

KING'S COLLEGE HOSPITAL, Denmark Hill, S.E.5.—Junior Obstetric and Gynaecological Surgeon.

LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.1.—Dermatologist.

MANCHESTER: ANCOATS HOSPITAL.—(1) Resident Medical Officer (male). (2) Pathological Registrar. Salary at the rate of £175 and £100 per annum respectively.

MANCHESTER: CHRISTIE HOSPITAL—Cancer Research Worker. Stipend £500 per annum.

METROPOLITAN ASYLUMS BOARD.—(1) Assistant Medical Officers of the Infectious Hospitals Service; salary £500 per annum. (2) Junior Assistant Medical Officer for the Hospital for Children, Sutton; salary £500 per annum.

METROPOLITAN HOSPITAL, Kingsland Road, E.8.—Honorary Anaesthetist (male).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Assistant Ophthalmic Surgeon.

NOTTINGHAM GENERAL HOSPITAL.—Pathologist. £350 per annum and fees for private work.

OLDHAM ROYAL INFIRMARY.—House-Surgeon to the Male Wards. Salary at the rate of £200 per annum.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.15.—Honorary Anaesthetist. Honorarium £20 annually.

ROYAL CHEST HOSPITAL, City Road, E.C.1.—(1) Physician with charge of Out-patient. (2) Radiologist (honorary).

ROYAL NORTHERN HOSPITAL, Holloway, N.—Assistant Pathologist. Salary £150 per annum.

ST. MARY'S HOSPITAL, Institute of Pathology and Research, W.—Research Studentship. Salary £200 per annum.

ST. PETER'S HOSPITAL FOR STONE, etc., Henrietta Street, W.C.2.—House-Surgeon. Salary at the rate of £75 per annum.

SALFORD ROYAL HOSPITAL.—(1) House-Surgeon. (2) Casualty House-Surgeon. Salary at the rate of £125 per annum each.

SARAFEN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W.1.—(1) Surgeon to In-patients. (2) Surgeon to Out-patients.

SHEFFIELD ROYAL HOSPITAL.—Honorary Radiologist in charge of Electro-therapeutic Department.

STOCKPORT COUNTY BOROUGH.—Assistant Medical Officer of Health. Salary £600 per annum, rising to £650.

SUDAN MEDICAL SERVICE.—Two Medical Inspectors, unmarried and under 30 years of age. Pay £E.720 a year, rising to £E.1,200.

UNIVERSITY COLLEGE HOSPITAL, Gower Street, W.C.1.—Obstetric Physician.

WAKEFIELD: WEST RIDING COUNTY COUNCIL—District Tuberculosis Officer for the Dewsbury Area. Salary £600 per annum, rising to £750.

WEST LONDON HOSPITAL, Hammersmith Road, W.6.—(1) House-Physician. (2) Two House-Surgeons (Male). Salary at the rate of £100 per annum.

WILMSEY GENERAL HOSPITAL, Harlesden Road, N.W.10.—Assistant Honorary Radiologist.

This list of vacancies is compiled from our advertisement columns, where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

## APPOINTMENTS.

AITKEN, William S.M.B., Ch.B.Glas., Medical Officer and Public Vaccinator to the Govanhill District of the Govan Parish Council, Glasgow.

BYRD, C. B. M.R.C.S., L.R.C.P., Certifying Factory Surgeon for the Patterdale District, Co. Westmorland.

CHELTENHAM GENERAL HOSPITAL.—Honorary Physician: F. J. Liddle, M.B., M.R.C.S., B.S., D.P.H. Honorary Pathologist: J. B. Davey, M.B., M.R.C.S., L.R.C.P., D.T.M.

ST. PAUL'S HOSPITAL FOR SKIN AND GENITO-URINARY DISEASES.—*Honorary Surgeon*: Kenneth Walker, M.B., F.R.C.S. *Honorary Assistant Surgeons*: Sir Thomas J. Carey Evans, F.R.C.S., H. P. Winsbury White, F.R.C.S.

ST. THOMAS'S HOSPITAL.—*Surgical Registrar*: C. V. Patrick, M.B., B.Ch., Cantab., F.R.C.S. Eng. *Casualty Officers and Resident Anaesthetists*: E. C. Archer, M.R.C.S., L.R.C.P., T. H. Sims, M.B., B.Ch., R. H. T. Rea, M.B., B.Ch., R. D. Alexander, M.B., B.Ch., D. P. Marks, M.R.C.S., L.R.C.P., R. H. Boggan, M.R.C.S., L.R.C.P., A. R. Robinson, M.R.C.S., L.R.C.P., A. A. Battison, M.B., B.S. *Resident House-Physicians*: A. M. Cooke, M.B., B.Ch., H. F. Turner, M.B., B.Ch., L. G. L. Walker, M.R.C.S., L.R.C.P., W. W. McLean, M.R.C.S., L.R.C.P.; (for Children) J. W. Hope-Simpson, M.B., B.Ch. *Resident House-Surgeons*: W. G. Thwaites, M.R.C.S., L.R.C.P., W. H. Gervis, M.B., B.Ch., M. W. P. Thudum, M.R.C.S., L.R.C.P., S. Starkey, M.R.C.S., L.R.C.P. *Resident Orthopaedic House-Surgeons*: A. P. Jeffery, M.B., B.S. *Resident House-Surgeons*: (Ear) F. C. Allan, M.R.C.S., L.R.C.P.; (Throat) R. McD. Barron, M.R.C.S., L.R.C.P. *Obstetric House-Physicians*: (Senior) A. F. D. Darlington, M.C., M.R.C.S., L.R.C.P.; (Junior) E. J. Rees, M.R.C.S., L.R.C.P. *Ophthalmic House-Surgeons*: (Senior) W. E. Heath, M.R.C.S., L.R.C.P.; (Junior) C. D. Gordon, M.R.C.S., L.R.C.P. *Chief Assistants and Clinical Assistants*: (Throat) D. F. A. Neilson, F.R.C.S. (Chief Assistant), J. B. Cavenagh, M.C., M.B., B.Ch., D. O. R. Pilot, M.R.C.S., L.R.C.P., C. R. Cooper, M.B., B.Ch., H. Yates, M.B., B.Ch.; (Skin) H. T. Barron, M.D. (Chief Assistant), W. E. Rees, M.R.C.S., L.R.C.P., F. G. Macdonald, M.R.C.S., L.R.C.P.; (Ear) H. I. Varrucy, F.R.C.S. Ed. (Chief Assistant), A. D. Pegg, M.R.C.S., L.R.C.P., E. W. P. Thomas, M.R.C.S., L.R.C.P.; (Dental) P. Lloyd-Williams, M.R.C.S., L.R.C.P., L.D.S. (Chief Assistant), (Children's Medical) J. D. Niles, M.B., B.Ch., J. P. Marsden, M.R.C.S., L.R.C.P., E. A. Trim, M.R.C.S., L.R.C.P., L. C. Cook, M.R.C.S., L.R.C.P.; (Tuberculosis Department) D. Riley, M.R.C.S., L.R.C.P., G. W. S. de Jersey, M.R.C.S., L.R.C.P.; (Orthopaedic) H. W. Nicholson, M.R.C.S., L.R.C.P.; (Electro-cardiograph) B. E. Thompson, M.B., B.Ch.; (X-ray Department) B. Shires, M.B., Ch.R.Ed. (Chief Assistant), (Mental Diseases) J. Rickman, M.B., B.Ch. (Chief Assistant), F. H. Macdonald, M.R.C.S., L.R.C.P.; (Antenatal) G. R. Marcano, M.R.C.S., L.R.C.P., J. J. R. Robinson, M.R.C.S., L.R.C.P.; (Electro-therapeutic) P. Bauwens, M.R.C.S., L.R.C.P.; (Ophthalmic) K. G. W. Saunders, M.R.C.S., L.R.C.P.

## DIARY OF SOCIETIES AND LECTURES.

ROYAL SOCIETY OF MEDICINE.  
Section of Tropical Diseases of Parasitology: Mon., 5.30 p.m., Dr. H. L. Meleney: Kala-azar in China. Histological sections and lantern slides will be shown.

Sections of Epidemiology, Comparative Medicine, and Disease in Children: Adjourned Discussion: Mon., 8 p.m., The Control of Tuberculosis and the Milk Supply. Speakers: Dr. M. J. Rowlands, Steinhilber Williams, D. Nabarro, Sir Layton Blewett, Dr. M. Raw, Mr. G. P. Hale, Sir Henry Gauvain, and Dr. A. Stanley Griffiths.

Section of Orthopaedics: Tues., 5 p.m., Cases.

Section of Pathology, Lister Institute, Chelsea, S.W.1: Tues., 8 for 8.30 p.m. Demonstrations:—T. Lumsden: Effects of an Anti-rum on Cancer Cells *in vitro*; H. Schultze and S. Zilvin: Experimental Tubercle in Rats. Communications.—V. Korenchewsky: Technique for Accurate Study of Metabolism in Rabbits; V. Korenchewsky and M. Cary: Internal Secretion of Sexual Glands; R. St. J. Hinks: Serological and Biochemical Reactions of Pathogenic Plant Bacteria; J. C. G. Ledingham: The Guarnieri Body; S. P. Hedson, H. B. Maitland, and M. Burbury: The Guinea-pig in the Guinea-pig.

Sections of Bacteriology and Pathology: Tues., 8.30 p.m., and State Medicine, 5.30 p.m., Special Discussion: The Nature, Prevention, and Treatment of Fibrosis. Openers: Dr. W. Edgecombe, Dr. J. A. Glover, Sir William Wilcoxon, and Dr. P. H. Hume. (Other speakers: Dr. A. C. L. Middelton, Dr. Kerr Pringle, Sir Percy Bassett-Smith, Dr. R. H. Hiff, Mr. J. E. R. McDonagh, Dr. M. B. Ray, Dr. Oliver Heath, Dr. C. E. Sandfield, Dr. Higgins.)

Section of Surgery: Wed., 8.30 p.m., Mr. Pintail Sai (Bangkok): Case of Sarcoma of the Breast. Discussion on the Mortality of Appendicitis, to be opened by Mr. Joseph Adams and Mr. McNeill Love.

Section of Obstetrics and Gynaecology: Thurs., 8 p.m., Specimens. Dr. J. S. Fairbairn and Dr. J. McNeill. Topics: Toxaemia in Early Pregnancy with Jaundice, Hyperemesis, and Multiple Neuritis. Mr. Everard Williams and Dr. Russell Reynolds: Determining Patency of Fallopian Tubes by X-rays. Dr. Sidney Forsdike: Investigation of Uterus and Tube by Inflation and X-rays.

Section of Laryngology: Fri., 4 p.m., Cases.

Section of Anaesthetics: Fri., 8.30 p.m., Mr. F. S. Rood: Extradural Anaesthesia.

Section of Otolaryngology: Sat., 9.45 a.m., Cases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.1.—Thurs., 5 p.m., Milroy Lecture by Dr. S. MacNalty: Epidemic Diseases of the Central Nervous System.

HUNTERIAN SOCIETY, Mansion House, E.C.—Mon., 9 p.m., Hunterian Oration by Dr. H. Letheby Tidy: Angio-haemic Anaemia.

MANCHESTER MEDICAL SOCIETY.—Joint meeting with Liverpool Medical Institution at Liverpool, Thurs., 4 p.m., Professor A. Ramsbottom: Dizzy Attacks. Mr. J. B. Macalpine: Treatment of Vesicle Papilloma; Mr. Harry Platt: Loose Bodies in Joints.

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1.—Wed., 9 p.m., Second Lettsomian Lecture by Sir Bernard Spotsbury: Wounds and Other Injuries in their Medico-legal Aspect.

## POST-GRADUATE COURSES AND LECTURES.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Mon., 5.30 p.m., Lecture: Renal Disease—its Diagnosis and Treatment. *Royal Waterloo Hospital*, Waterloo Road, S.E.1: Special Course in Medicine, Surgery, and Gynaecology. Lecture Demonstrations in the Wards and Out-patient Departments. *North-East Fester Hospital*, St. Ann's Road, Tottenham, N.15: Wed. and Thurs., 11 a.m., Demonstrations on the Diagnosis and Treatment of the Acute Infectious Diseases.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, W.C.1.—Thurs., 4 p.m., Some Haemorrhagic Affections in Childhood.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C.1.—Mon., Tues., Thurs., and Fri., 2 p.m., Out-patient Clinics. Mon., 12 noon, Cerebellum; 3.30 p.m., Chorea. Tues., 3.30 p.m., Pathology of 12 noon, Tumours. Wed., 3.30 p.m., The Oculomotor Nerve. Thurs., 12 noon, The Nerve; 3.30 p.m., Radiology in the Diagnosis and Treatment of Nervous Cases. Fri., 3.30 p.m., Surgical Treatment of Spastic Conditions. Operations: Tues. and Fri., 9 a.m.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.15.—Dr. J. In-patient and Out-patient Clinics, Operations, Clinics in Special Departments. Lectures and Demonstra-

tions: Tues., 4.30 p.m., Treatment of Diabetes. Fri., 4.30 p.m., Nasal Catarrh.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone Road, N.W.1.—Thurs., 5 p.m., Common Obstetric Difficulties.

ST. JOHN'S HOSPITAL, 43, Leicester Square, W.1.—*Chatterfield Lectures*: Tues., 5 p.m., Neph. Thurs., 5 p.m., Benign Growths of the Skin.

W. J. LOYD'S POST-GRADUATE COLLEGE, Hanover-square, W.—Mon., 12 noon, Applied Anatomy. Tues., 12 noon, Chest Cases. Wed., 12.15 p.m., Medical Pathology. Thurs., 2 p.m., Genito-Urinary Department. Fri., 12 noon, Surgical Pathology. Sat., 10 a.m., Medical Diseases of Children. Daily 10 a.m. to 5 p.m., Sat. 10 a.m. to 1 p.m., In- and Out-patients, Operations, Special Departments.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Gower Street, Ballham, S.W.12.—Wed., 4 p.m., Eye Cases.

GLASGOW POST-GRADUATE MEDICAL ASSOCIATION.—At Royal Infirmary: Wed., 4.15 p.m., Venereal Diseases (Male).

LIVERPOOL UNIVERSITY MEDICAL SCHOOL.—3.30 p.m. Mon., Children's Hospital: Surgical Diseases of the Kidneys in Childhood. Tues., Southern Hospital: Treatment of Whitlows. Wed., Northern Hospital: Subinfections. Thurs., Stanley Hospital: Ovarian Tumours.

## British Medical Association.

OFFICES AND LIBRARY, 423, STRAND, LONDON, W.C.2.

### Reference and Lending Library.

THE READING ROOM, in which books of reference, periodicals, and standard works can be consulted, is open to members from 10 a.m. to 6.30 p.m., Saturdays 10 to 2.

LENDING LIBRARY: Members are entitled to borrow books, including current medical works; they will be forwarded if desired, on application to the Librarian, accompanied by 6d. for each volume for postage and packing.

### Departments.

SUPREMACY: (Financial Secretary and Business Manager) Westland, London.  
MEDICAL: (Secretary) Westland, London.  
EDITOR: (Telegrams) Atiology Westland, London.  
Telephone number for all departments: Gerrard 2520 (5 lines).

SCOTTISH MEDICAL SECRETARY: 6, Rutland Square, Edinburgh. (Telegrams: Associate, Edinburgh. Tel.: 4261 Central.)  
IRISH MEDICAL SECRETARY: 16, South Frederick Street, Dublin. (Telegrams: Baclilus, Dublin. Tel.: 4737 Dublin.)

### Diary of the Association.

3 Tues. London: Organization Committee, 2 p.m.  
County Division: Coventry and Warwickshire Hospital, 8.30 p.m.  
South-West Essex Division: Woodford Jubilee Hospital, Woodford Green. Paper by Mr. C. H. S. Frankau on Tuberculous Glands of the Neck, 3.30 p.m.

4 Wed. London: Medico-Political Committee, 2.30 p.m.  
Cambridge Division: Berners and Rotherhithe Hospital, Lower Road, Rotherhithe. Address by Dr. N. Mutch on Rheumatoid Arthritis, 9 p.m.

5 Thurs. London: Journal Committee, 2.30 p.m.  
Edinburgh: Scottish Committee.  
Guildford Division, Royal Surrey County Hospital, Guildford. Discussion on Abdominal Pain, to be opened by Sir Crisp English.  
Staffordshire Branch: Stork Hotel, Walsall, 4 p.m. Dinner, 6.15 p.m.

6 Fri. London: Dominions Committee, 2.30 p.m.  
Exeter Division: Royal Devon and Exeter Hospital. Lecture by Dr. W. Gorion on the Significance of Recent Work in Cardiology, 5.30 p.m.

10 Tues. City Division: Metropolitan Hospital, Kingsland Road. Paper by Sir H. E. Bruce-Potter on Medical Practice and its Pitfalls, 9.30 p.m.

11 Wed. London: Finance Committee, 2.30 p.m.

12 Thurs. London: Joint Meeting of Representatives of Divisions and of Local Medical and Panel Committees, together with Members of Council, Insurance Acts and Royal Commission Committees, re Evidence to be given by Association before Royal Commission on National Health Insurance, Wesleyan Central Hall, Westminster, London.

MANCHESTER: ASHCOTT HOSPITAL.—Thurs., 4.30 p.m., Dyspepsia.  
MANCHESTER: ROYAL INFIRMARY.—Tues., 4.15 p.m., Practical Points in Diabetes.

MANCHESTER: ST. MARY'S HOSPITAL.—Whitworth Street West Branch: Fri., 4.30 p.m., Displacements of the Uterus in Relation to Pregnancy and Labour.

ST. ANDREWS INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.—Tues., 4 p.m., Albuminuria and Pregnancy. (March 10th, Albuminuria and the Specific Fevers. March 17th, Diuretics.)

## BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

### BIRTH.

McDONNELL.—On February 19th, at 89, Lower Baggot Street, Dublin (Quaker home), to Sheila, the wife of J. J. McDonnell, M.B., a daughter.

### DEATHS.

GETTINGS.—On February 18th, at Hammerwich, near Lichfield, Cathbert Key Gettings, M.B., Ch.B. (Irm.), M.R.C.S. Eng., L.R.C.P. Lond., aged 45, eldest surviving son of J. S. Gettings, surgeon.

MARTIN.—On February 19th, at "Strangford," Church Road, Ashford, Kent, Albert Edmund Samuel Martin, F.R.C.S. (Irel.), aged 41.

MASON.—On Saturday, February 21st, at his residence, Torkington House, Stamford, James Mason, M.D., aged 85 years. Interred at Hauxwell Cemetery, Wednesday, February 25th.

## PROCEEDINGS OF COUNCIL.

· · This was agreed to.

*Charles Hastings Collection: Gift to Association.*

The Chairman stated that the Worcester Medical Society, through the Worcester Division, had offered the majority of the books in its library to the British Medical Association. The society was formed about 1860, but was now practically defunct. Some of the books in the library had been presented by the founder of the Association, Sir Charles Hastings. Mr. W. G. Spencer, the Association's Honorary Librarian, was strongly of opinion that the whole of the gift should be accepted, quite a number of the books being of considerable classical and historical value. Some of the books were duplicates of those already in the Association's library, but Mr. Spencer thought that even these could be made use of.

Mr. Turner moved, and Dr. Goodbody seconded, that the offer be accepted, with an expression of gratitude to the Worcester society for the gift, and this was agreed to with applause. The Chairman stated that evidently the library was formed upon the collection left by Sir Charles Hastings, and that it might be possible to keep the nucleus of the collection separate and distinctive in the library of the Association.

*Courageous Act of Assistant Medical Secretary.*

The Chairman made reference to the courageous act of a member of the staff, Dr. C. Courtenay Lord, Assistant Medical Secretary, who, during the Christmas holidays, was on the scene of a motor-car accident and was instrumental in saving life in a way which earned much public appreciation. He thought it would be the wish of the Council to put on record its own appreciation of Dr. Lord's action in extraordinary and difficult circumstances, and he moved the following resolution:

The Council of the British Medical Association has heard with great pleasure of the gallant conduct of Dr. C. Courtenay Lord, Assistant Medical Secretary, on December 28th, 1924, when at Stokesay Bridge, Shropshire, he took the leading part in saving the lives of two persons who were in danger of drowning in the river Ounay, as a consequence of a motor-car accident; and also rescued a third person who afterwards died. The Council hereby places on record its admiration of his courageous action and its congratulations to Dr. Lord.

The resolution was carried with applause. Dr. Lord thanked the Council. He said that he never expected that any official notice would be taken of what he had done; it was merely his good fortune to have been in the right place at the right time.

*Puerperal Morbidity and Mortality: Appointment of a Committee.*

The Council at its previous meeting passed a resolution that it was unable to accept the opinions expressed in Dame Janet Campbell's Report on Maternal Mortality, issued by the Ministry of Health, as to the causation of puerperal morbidity, and the inferences, especially to the disadvantage of general practitioners, which had been drawn therefrom. Mr. Turner, chairman of the Medico-Political Committee, now proposed that a special committee of the Association be set up to consider and report on the causation of puerperal morbidity and mortality and on the administrative action, if any, that should be taken in connexion with the matter. Dr. Flemming supported the motion, stating that more information was needed than up to the present had been available. He considered that there had been unjust criticisms of general practitioners in this matter, and that a proper setting out of the facts would alter public opinion on this question very considerably. The Chairman of Council reported that a letter, covering a report from a committee of the Obstetrical Section of the Royal Society of Medicine on the subject, had been received from Sir G. Newman, who had asked for an expression of opinion on behalf of the Association.

The motion was agreed to, and after some discussion the following were nominated to form the committee: the officers of the Association, Mr. E. B. Turner, Dr. C. E. S. Flemming, Dr. J. W. Bone, Sir Ewen Maclean, Mr. Comyns Berkeley, Dr. Christine Murrell, Dr. Mabel Ramsay, Dr. H. J. Cardale, Dr. C. E. Douglas, Dr. W. E. Thomas, Dr. G. F. Buchan, and Sir Jenner Verrall, with power to co-opt not more than two additional members.

*The General Medical Council and the Public Prosecutor.*

A long discussion took place on a matter brought forward by the Medico-Political Committee, following upon a resolution passed by the Medical Defence Union. This concerned a case in which a practitioner was brought before the General Medical Council on a charge arising out of information laid by the Director of Public Prosecutions; but before the reference to the General Medical Council an investigation had been carried out by the police, who, however, had not proceeded with the charge. The General Medical Council came to the conclusion that the accused practitioner was innocent and dismissed the complaint. After various views had been expressed it was

eventually agreed that the Medico-Political Committee should reconsider its report in the light of the discussion, and bring up a recommendation at the next meeting of Council. The question of the position of members of the profession in respect to possible charges against them in the courts—a question which had arisen on a communication from the West Birmingham Branch of the General Practitioners' Union, and which had a special reference to the case of *Rex v. Bateman*—was also remitted to the Medico-Political Committee for report, and the hope was expressed that by the time the Committee came to consider its report the considered judgement in the *Bateman* case might be available.

*Indirect Methods of Advertising.*

Dr. Langdon-Down, chairman of the Central Ethical Committee, brought forward a revised report of the Committee dealing with indirect methods of advertising. He recalled the debate at the Annual Representative Meeting at Bradford, when general approval was given to the report on this subject, but reconsideration was requested with regard to the paragraphs dealing with anonymity in the press so as to make more clear the occasions when and the conditions under which it was possible to depart from such anonymity. The Committee had done its best to draft paragraphs which should offer a guiding rule on the subject. The revised paragraphs ran as follows:

12. From time to time there are discussed in the lay papers topics which have relation both to medical science and policy and to the health and welfare of the public, and it may be legitimate or even advisable that medical practitioners who can speak with authority on the question at issue should contribute to such discussions. But practitioners who take this action ought to make it a condition of publication that laudatory editorial comments or headlines relating either to the contributor's professional status or experience shall not be permitted; that his address or photograph shall not be published; and that there shall be no unnecessary display of his medical qualifications and appointments. There is a special claim that practitioners of established position and authority shall observe these conditions, for their example must necessarily influence the action of their less recognized colleagues. Discussions in the lay press on disputed points of pathology or treatment should be avoided by practitioners; such issues find their appropriate opportunity in the professional societies and the medical journals.

13. After making all allowances for all those modes of publicity for which there may be some justification, there remain many instances which can only be regarded as gravely and unnecessarily contravening the spirit of the notice of the General Medical Council. The Association is convinced that in taking up an attitude of determined opposition to these undesirable journalistic methods, the Association is acting in the best interests of the public as well as of the medical profession. The extension of the system can only lead to a competition for public notice in which the able and more scrupulous men would be left behind by those who professionally are greatly inferior, to the detriment of the public, who are ill qualified to judge of the true worth of scientific opinions. The extension of the advertising habit among the profession in general would certainly destroy those traditions of dignity and self-respect which have helped to give the British medical profession its present high status, and would gravely undermine the amenities and harmonious working of medical practice.

Dr. Fothergill contested the phrase in the second of these paragraphs, "the able and more scrupulous men would be left behind by those who professionally are greatly inferior"; he said that because a man started to advertise himself it did not at all follow that his abilities were inferior. He proposed that the phrase should read, "... in which the more scrupulous men would be left behind, to the detriment of the public." Dr. Langdon-Down saw no reason for accepting this amendment, but Dr. Fothergill, who was seconded by Colonel Rait, pressed it to a vote, and the amendment was carried.

Dr. Hawthorne said that he did not dissent from the propositions contained in these revised paragraphs provided it was recognized that they were based upon a certain principle which must have a general application. The principle upon which medical conduct might be prescribed was one or other of the following: (1) to allow every man to act according to his own sense of good taste and personal self-respect; (2) to lay down certain rules which were based upon the view that it was not in the public interest that professional qualifications and achievements should be openly displayed, on the ground that the public had not the information which entitled them to judge of the value of these displays. The principle which had been adopted in this case was the second of these two. But if it was proposed to assert this principle its proposers must be ready to apply it, not in a limited field, but in the whole field of publication. There were certain publications which gave an opportunity to medical practitioners to display their professional achievements, their addresses, their telephone numbers, the numbers of their motor cars, and the occupations of their leisure. It must not be said of any legislative body in the profession that it was ready enough to inflict penalties for transgressions when small and unprotected practitioners were concerned, but allowed members of the

profession more highly placed to go free. In South Africa recently it had been specifically pointed out that it was an offence against medical ethics to construct medical autobiographies for publication in social volumes of the quality of *Who's Who*. A member said it was stretching the argument very far to suggest that members of the public would be likely to search through the entries in *Who's Who* in order to select a practitioner.

It was agreed to recommend the revised report to the Representative Body.

#### *Advertising of Nursing Homes.*

Dr. Langdon-Down brought forward a recommendation of the Central Ethical Committee relating to the question of the advertising of nursing homes. He reminded the Council that while the greater part of this recommendation had been agreed to on a previous occasion, one paragraph had been sent back to his committee for further consideration. His committee, however, was unable to see any reason for modifying the paragraph, and accordingly resubmitted it as follows:

That if a medical practitioner has a financial interest in any institution to which he refers a patient, it is not consonant with professional integrity that a knowledge of such interest be withheld from the patient.

Dr. Brackenbury said that, like Dr. Hawthorne in regard to the previous question, he had a great respect for principles, but when a principle was enunciated in this rather strong form, without proviso or exception, he assumed it was to be universally applied. He knew of a doctor who had lent a considerable sum of money to a matron to enable her to set up a nursing home, but beyond the loan he had no financial interest whatever in the venture. He would not receive any gain; he might possibly suffer loss. Was he to be compelled to explain these circumstances to every patient?

Dr. Radcliffe suggested the qualifying words after "financial interest," "involving his possible pecuniary gain." Dr. Langdon-Down said he was rather doubtful whether the case instanced by Dr. Brackenbury came strictly within the term "financial interest," but he agreed that the words suggested by Dr. Radcliffe would meet that particular objection, and he was prepared to accept them.

The recommendation was carried as follows:

That the Council is of opinion that if a medical practitioner has a financial interest, involving his possible pecuniary gain, in any institution to which he refers a patient, it is desirable that he should disclose this fact to his patient.

#### *Door-plates.*

Dr. Langdon-Down said that a member of the Association had recently inquired whether it was in order for a medical man who was practising as an eye specialist to put on his door-plate "Ophthalmic surgeon." The opinion of the Committee was that it was undesirable to use a title on a door-plate indicative of special practice. The President of the General Medical Council, however, in a reply to a similar inquiry, stated that as no exception had been taken to the description of "Dental surgeon" by a medical man practising dentistry, it might be inferred that the Council would raise no objection to the words "Ophthalmic surgeon" used upon a plate. In answer to this the Committee had pointed out that the designation "Dental surgeon" stood in rather a different category, because it conveyed information to which it was reasonable that the public should have access, but in the case of other specialties the proper procedure on the part of the patient was not to go direct to a practitioner who professed to be a specialist, but first to seek the advice of his ordinary medical attendant. A further letter had now been received from the General Medical Council, stating that the matter had been brought before the Executive Committee, and that while the Council, for which it spoke, would deprecate any extension of the custom of announcing special departments of practice, each case must be considered on its merits, and the Council would be unlikely to find a charge of advertising proved in this particular instance.

#### EVIDENCE BEFORE THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

The Council then turned to the consideration of the revised draft Memorandum of Evidence (printed as revised by the Council in last week's SUPPLEMENT) proposed to be placed before the Royal Commission on National Health Insurance. The Treasurer took the chair, and Dr. Bolam explained the alterations which had been made in the Memorandum after considering the replies to the questions set out, which had been sent from more than 200 meetings of practitioners held throughout the country.

Dr. Bolam said that the introduction to the revised Memorandum was almost entirely the work of the Medical Secretary, and it set out very clearly the right of the British Medical

Association to appear as representing the profession before the Royal Commission. The material amendments in the body of the Memorandum were not very large. For the most part they were found in Section A, dealing with persons to be provided for. Paragraph 11 of the original draft had been rearranged, and the general argument of the ensuing paragraphs somewhat reworded so as to emphasize, what the framers of the draft had in mind from the first, the importance of providing a family doctor for the persons under consideration rather than the setting up of a system of treatment centres with State-paid or rate-paid medical officers. Paragraph 13 was one of the most difficult to phrase in order to convey the opinion expressed in the local meetings throughout the country. Inevitably those who thought in one direction would be of opinion that the revised paragraph did not go far enough, while others who took a different view would believe that it went too far. The committee in charge of the draft had tried faithfully to convey the balance of opinion with regard to this question of dependants. In Section B there was very little alteration, and such alterations as there were gathered round the difficult question of the maternity service. Dr. Bolam added, in conclusion, that all the resolutions sent up from the local meetings had been carefully considered at a joint meeting of the Insurance Acts and Royal Commission Committees; a number of the points brought forward had been incorporated in the draft, and certain others had been noted by those who would present the evidence and make submissions by word of mouth.

Dr. Fothergill considered that the document still did not state adequately the opinion of the profession with regard to persons who could and persons who could not pay for themselves. He wanted it definitely stated at the beginning of paragraph 12 that there were four groups of persons requiring medical service—namely, (1) those who without assistance could pay the fee charged, either at the time or later; (2) those who could pay the premium in full for an insurance scheme; (3) those who could pay only a portion of the premium required for such a scheme; and (4) those who were unable to pay any part of such premium. The first two of these classes must be left out of the scheme.

Dr. Brackenbury said that he appreciated the motive lying behind this suggestion, but to amend the draft in this way would complicate matters, because there a distinction was drawn between insurance premiums wholly paid by the patient, premiums paid partly by the patient and partly by his employer, and premiums paid partly by the patient, partly by the employer, and partly by the State. But it was important to make the distinction clear between those who ought not to be in the scheme at all and those who ought. He felt that if the paragraphs as now drafted were carefully read it would be found that the right emphasis had been made. The desire of those who were putting forward this evidence was to limit the persons to be provided for in any scheme to a greater extent than they were limited now.

Dr. Fothergill, who had put forward his views on this point in the form of an amendment, withdrew it after this explanation.

Mr. Turner, who said that the Memorandum now was much more satisfactory than when it was first presented to the Council, challenged Dr. Bolam's statement that the balance of opinion in the profession was in favour of the inclusion in the insurance scheme of the dependants of the lower-paid persons. If the replies from the different areas were analysed according to the way in which voting took place in the Representative Meeting he believed a majority would be found to be against the proposal. He did not think that this would command a majority in the Association, or if there was such a majority that it would appear from the summary of replies received to be negligible.

Dr. Stevens also said that there was no evidence that the profession throughout the country was in favour of the inclusion of dependants. These proposals were the slippery path which would lead to the inclusion of practically the whole population. He complained of the opportunism of the proposals.

Dr. Bolam said he was prepared to assert quite explicitly that the balance of opinion in the profession was in favour of what was set out under this head in the Memorandum. The majority might be "negligible," but under a democratic constitution a majority could not be neglected. If the figures were analysed it would be found that in addition to the 87 areas which had answered "Yes" to the question whether they favoured the inclusion of the dependants of lower-paid persons, at least 11 others had practically registered the same decision, accompanying it with suggestions designed to safeguard the position, which was indeed already safeguarded in these respects; on the other hand, 70 areas had answered "No," but among those which had qualified their replies only two had answered in this direction, so that the true numbers were 98 to 72, leaving out of account 25 areas which favoured inclusion of all dependants. The balance of opinion—he stressed it no more than that—was in favour of the inclusion.

Mr. Turner said that the vote of Marylebone, with some 500 or 600 members, which was against the proposal, counted only for one in this summary, just like some Division with 40 or 50 members.

Dr. Brackenbury said that if Mr. Turner and Dr. Stevens would read the document in its final form he did not think they would find in it a statement the accuracy of which they could challenge, even as an expression of opinion.

Mr. Turner, speaking with regard to paragraph 15, asked how many members of the Council really thought that an income limit would be imposed which would cut out the higher-paid manual workers. He was sure that many areas assented to this proposal under the impression that the income limit such as here set out might be obtained. There was no possibility of such an income limit being conceded. What the Commission was likely to say was that apparently the Association was in favour of including in any circumstances two-thirds of the population, and they might as well bring it up to the 38,750,000 set out in paragraph 14. There were trade unionists on the Commission some of whom wished for a State medical service, and they were not likely to impose any income limit whatever.

Dr. Brackenbury said that in this evidence the profession was not stating what it thought it was going to get, but what it thought it ought to have. He was not so pessimistic as Mr. Turner with regard to the eventual results, but even if he were he would still consider it the duty of the profession to put forward the right suggestions. There was no need to be frightened about an income limit. There were three or four income limits in the present system. He saw no administrative difficulty in making a distinction between those insured persons whose dependants were included and those whose dependants were not included. Nor was there anything sacrosanct about the income limit of £250. It might be lower, and if it was made sufficiently low it might be possible for the profession to agree to include the whole of these dependants on the same basis.

Dr. Buchan, speaking with regard to the last part of paragraph 17, said that if the insurance system was to be a system of preventive medicine the general practitioner should, in his opinion, do the work which it was suggested in the Memorandum should be done in clinics—the instruction of mothers and the routine examination of infants and young children—and if it was suggested by the framers of these proposals that the general practitioner should not do this work, but that it should be relegated to others, it seemed to him not in harmony with the protestations made on behalf of the general practitioner. With regard to paragraph 18, which laid it down as essential that the interests of Poor Law officers affected by the proposed changes should be the subject of special provision, he hoped that this provision would not be confined to Poor Law officers, because other medical officers would be displaced under such a scheme.

Dr. Bolam said that the Association would keep an eye on all interests affected.

Sir Richard Luce, speaking with regard to paragraph 24, said that he did not like this proposal for panel consultants. It would be very much better if it were left to any registered medical practitioner who was willing to undertake this service. There was only one exception he would suggest—namely, that it should not be considered right, save in very exceptional circumstances, for a practitioner to call in his partner.

Dr. Brackenbury said that no Government would pay specialist fees without being assured of some satisfactory standard of specialist knowledge and experience. There might, however, be a system of general practitioner consultation, with fees.

Dr. Radcliffe pointed out that there were many members of the profession who were part-time specialists and part-time general practitioners.

A long discussion then ensued on paragraph 29, relating to maternity work. Dr. Johnson expressed himself as totally opposed to the bringing in of maternity work under the Insurance Act. He could not see what benefit the proposals would confer, other than those available already, to the pregnant or parturient woman, and to the practitioner any such scheme must be accompanied by harsh restrictions; moreover, nothing was said about the amount of remuneration.

Dr. Brackenbury pointed out that the Council agreed to these proposals on the last occasion, and this agreement had since been emphasized at meetings throughout the country. An important point in the scheme was that there would be complete liberty for a practitioner to accept or refuse this kind of work. But he thought it would be a mistake to let the Government regard maternity work as something completely separated from ordinary practice or that it should proceed upon lines of its own without reference to other provisions made for public health. He was well aware of the difficulties attaching to this subject. The phrase "for maternity purposes only" did not mean attendance at the confinement only.

Dr. Flemming thought that the instances in which a woman would call in another medical man, not her insurance practitioner, to carry out this supervision would be very few. He thought that the scheme set out in paragraph 29 would have the result of bringing the general practitioner to a very much larger extent into the area of maternity work than in the past. Dr. Bolam expressed the hope that the Council would leave this paragraph as it stood. He believed that the situation was governed by the phrase, "any practitioner should be at liberty to place his or her name upon the list for maternity purposes only." Nine times out of ten no difficulty would arise, because the practitioner having the maternity supervision would also be the insurance doctor of the woman concerned.

Dr. Fothergill moved an amendment to substitute for the word "supervision" ["supervision during pregnancy"] the phrase "medical attendance," but this was lost.

Dr. Brackenbury said that it was possible to pose all sorts of different conundrums with regard to this paragraph, but in the great majority of cases, as Dr. Bolam had said, no difficulty would arise because it would be the ordinary insurance doctor who was in attendance. It was impossible to draft any paragraph dealing with the question of maternity without raising difficulties in one direction or another, but although these theoretical difficulties might seem to be formidable, in practice he believed they would not arise to any great extent.

The paragraph dealing with maternity work was, after some further discussion, agreed to. On paragraph 37 Dr. Fothergill moved to insert a third requirement on the part of the insured person—namely, "where his condition requires a home visit, to give notice to his doctor before . . . n.m., except in case of accident or other sudden emergency." Dr. Bolam thought that on a proper perspective this was a minor detail as compared with the importance of the general mass of evidence. The amendment was lost.

The remainder of the memorandum with the three appendices was then approved with one dissentient.

Discussion then took place on a second recommendation from the joint meeting of the Insurance Acts and Royal Commission Committees, that honorary secretaries of Divisions and of Local Medical and Panel Committees be requested to call further meetings of the local profession for the purpose of informing their representatives on the draft Memorandum previous to the joint conference to be held on March 12th. Dr. Brackenbury hoped that the matter would be left sufficiently fluid in the local meetings, and that not too rigid instructions would be given. Dr. Bolam also hoped that nobody would try to stand on technicalities or on dignity in this particular matter, so that the discussion at the joint conference might be as unfettered as possible.

The recommendation was agreed to.

Dr. Bolam then returned to the chair of the Council.

#### *Request for Representative Meeting.*

Three motions by Divisions—Eastbourne, Hastings, and Kensington—were on the agenda requesting that a special meeting of the Representative Body be called to consider and decide upon the evidence to be submitted by the Association to the Royal Commission. There was also a motion by Mr. Turner to the same effect.

Dr. Murrell moved the Kensington resolution. She said that the Kensington Division felt very strongly that a Representative Meeting would have a much more official status in dealing with this matter than any joint conference could have. Dr. Goodbody seconded. Dr. Fothergill pointed out that a report from the forthcoming conference could by one resolution be put to the Representative Body, and the likelihood was that it would be accepted. He was very jealous of the constitutional procedure. At present the Association had got not only a very large number of its members to acquiesce in its decisions so far formulated, including members ordinarily indifferent to medical politics, but it had also commanded the support of many non-members. He was perfectly certain, however, that if a new form of "medical parliament" were set up to make decisions—a parliament which would be composed to the extent of 80 or 90 per cent. of insurance practitioners—a good deal of unrest would be caused among many who had been entirely loyal to the Association. The Memorandum was going to determine the policy for the future. To have a Special Representative Meeting would involve no expense and no delay, and it would have the advantage of showing that the Council was acting constitutionally.

Dr. Brackenbury said that there was nobody who appreciated the onerous position of Chairman of the Representative Body more than he, its present holder, did. He thought that a Representative Meeting must be called if only to make it possible for the Association to pay the railway fares of those attending

the joint conference. If it was understood from the beginning that the reference to the Representative Body was to be entirely formal there would be no objection; but if it was not formal, and the Representative Body should desire to revise what had been or was to be decided by the conference, there would be difficulty in the conference itself, where the feeling that the Representative Body might override the decisions would be prejudicial to the kind of discussion which was desired. This was a unique occasion. Why not, if necessary, invoke a unique procedure? He hoped it might be felt that there in the conference the two bodies concerned were fully and freely discussing together the important situation which had arisen. Technically the conference would not be determining policy at all; it would be deciding as to the evidence which was to be given before the Royal Commission. It would be giving its imprimatur to a document which embodied in outline the evidence of the profession. He did not think that the call for a special Representative Meeting had any considerable backing. Mr. Turner might say, as he inferred in his motion, that independently of the conference the members of the Representative Body should come to their own conclusions. If that was so, it might possibly lead to disaster, although he did not think that in fact the Representative Body would come to any conclusion different from that of the conference. The important thing was to get all these people together in as free a position as possible without standing too much on technicalities.

Sir Jenner Verrall thought it evident that a decision by this joint conference could not be equivalent to a decision of the Representative Body. Nothing which took place at that conference could prevent individuals in the Representative Body from taking a different line at the next meeting. The proposed conference was really a corollary to the meetings which had been taking place all over the country, and in which it had been sought to express, not the view of the Association only, but of others outside the Association. Dr. Wallace Henry held that the difficulty might be got over by a recommendation to the Representative Body from the Council to accept the resolutions passed by the joint conference. Mr. Bishop Harman said that there was nothing to prevent separate votes being taken at the conference—those of representatives of Divisions on the one hand, and those of representatives of Local Medical and Panel Committees on the other. Then, if differences were found to arise between the two bodies constituting the conference, they might be settled in committee there and then. Mr. McAdam Eccles said that he was about to suggest the same thing. Dr. Hawthorne suggested that the Representative Meeting should take place first; the decision of that meeting, of course, would have great weight with the conference, and if the conference should take a different line it would still be open to those who went before the Royal Commission as witnesses to say that there was a minority who took a different view.

Dr. Bolam pointed out that there was not being put forward a policy which was irrevocable. He thought that the best procedure would be to convene a meeting of the Representative Body half an hour before the conference was due to open, the purpose of which meeting would be to authorize its members to attend the ensuing conference. In the conference itself he hoped there would be no question of the sheep on the one side and the goats on the other, but that a united front would be presented. The draft Memorandum of Evidence, after it had passed through the Council, would come back to the Council, and the Council would then decide definitely and finally the shape in which it would go to the Commission. The Council must take the responsibility of putting up this evidence. It must be borne in mind that a memorandum such as this could not be laid down as policy in every single strand of it; it was simply evidence upon which further evidence to be given verbally would depend.

Dr. Wallace Henry moved, as an amendment to the Kensington motion:

That the Council requests the Chairman of the Representative Body to call a special Representative Meeting for the purpose of authorizing the members to attend a subsequent conference in association with the representatives of Local Medical and Panel Committees.

Dr. Bone seconded, and this was agreed to with two dissents.

#### OTHER COUNCIL BUSINESS.

*The Case of Senior Surgeon Commanders.*  
Sir Richard Luce, M.P., chairman of the Naval and Military Committee, reported that since the last meeting of the Council, as a result of the long-continued efforts made by the Association to secure an increase in the amount paid to senior surgeon commanders on compulsory retirement, the Admiralty had raised its offer by £50; that is to say, instead of £250, these officers were now offered £300 (on a sliding scale) on their compulsory retirement before the normal expectation under the

1920 Regulations. His committee did not feel that this was adequate recompense, but the general belief was that this was all that was likely to be secured, and the committee was of the opinion that the offer should be accepted. He read a letter from the representative of the Navy Medical Service on the Council (Sir Percy Bassett-Smith) stating his view to the same effect and expressing appreciation of the great fight which the Association had put up over this matter. The acceptance of this offer carried with it the non-continuance of the attitude of this Association in advising members of the profession seriously to consider the disadvantages to which they were liable if they placed their careers in the hands of the Admiralty. The relations between the Association and the Admiralty would there and then start again with a clean sheet.

#### Medical Service in India.

Sir Richard Luce introduced the report of the Committee which had been set up by the Council to consider the proposals of the Royal Commission (the Lee Commission) on the Superior Civil Services in India. He said that the Committee was indebted to Sir Gerald Giffard, one of its members, for a very useful memorandum on the position, and this was circulated among the Council. By the Act of India, which was passed in 1919, the work of the medical services was placed entirely under the provincial Governments, save that the personnel of the I.M.S. attached to those provincial services was left to the Secretary of State. The recommendation of the Royal Commission was that the members of that service should in future be transferred to the provincial services and be under their entire control, one point only being reserved—namely, the requirement of the Government that there should be a certain proportion of European medical officers in each of these services, the proportion to be fixed and maintained by the Secretary of State. It appeared that this was being resisted by the provincial Governments, not only in theory but in practice. These Governments were not willing to receive British medical officers into their services, nor to assent to the principle that a fair share of the higher posts should be given them. The Committee in July last had recommended—a recommendation which was adopted by the Council—that the view should be presented to the Government that the transference of these medical officers to the provincial Governments would militate against getting medical officers to join the civil branch of the Indian Medical Service. When the Committee, however, went into the question further, after its reappointment, it came to the conclusion that the matter would have to be surveyed from a rather different point of view. The Committee now felt, after reconsideration, that by the original transference of the medical services to the provinces the damage had already been done, and that the further step recommended by the Lee Commission—the provincialization of the European medical officers—was an almost inevitable consequence. To resist that proposal, in the view of the Committee, would only hamper matters, and the better proposal as a *fait accompli*, to see how various things could be safeguarded. The first question was the provision of European medical attendance for the benefit of the European population. The Committee suggested that official medical attendance should not be provided for any civil servants by the Government of India, and that every civil servant should be free to make his own arrangements, employing for this purpose officers of provincial medical services and of private companies, civil medical practitioners, medical missionaries, or R.A.M.C. officers if and when available. Monetary compensation, of course, must be made to the civil servants for the loss of free medical attendance. With regard to the supply of medical officers for the purposes of the Indian Army, the proposal of the Committee was that the two existing military medical services should be amalgamated by the formation of an Army Medical Corps in India, the officers to consist of properly qualified men of Indian birth, together with R.A.M.C. officers serving under conditions analogous to those now obtaining in the case of officers of the Royal Engineers serving in India. The terms and conditions of service of the R.A.M.C. in India should be made more attractive than at present. The officers should be given permission to attend also held it to be fundamental that there should be in India a tightly qualified teaching staff, which it should be the business of the Government of India and the Secretary of State to maintain. The Government should invade the business of State to the extent of taking under its control all professional appointments, provision for research and public health, and post-graduate teaching. The establishment of a Ministry of Health in India was an immediate necessity. It was also desirable that the Government should encourage in every way possible the training of Indians as medical practitioners for the Indian population, but that no encouragement should be given to obsolete and unscientific systems of medicine.

Colonel Rait, who pointed out that what was now presented to the Council was diametrically opposed to the resolution of last July, moved an amendment, which he said was in the nature of a compromise and did not fully meet his own views, which he proceeded to elaborate in a speech made to the Council *in camera*. His amendment expressed the view that the present state of medical affairs in India should be allowed to continue until the whole situation came up for review in 1929; that in the meantime modern scientific medicine should be encouraged, and the ancient systems of medicine officially discountenanced; that steps should be taken to make the recruitment of medical men more popular by engendering a feeling of security and lessening the difficulty in being seconded to civilian employment; and that inducements should be offered to facilitate the entry of Indian gentlemen into the medical services by examinations in India as well as in London.

Dr. Fothergill urged that a deputation be sent to the Secretary of State to reaffirm the original position taken by the Council in July last, and that in the meantime the present report should be held over. Dr. Morton Mackenzie said that the primary trouble was the classification of the medical department as a "transferred subject" in India. Nothing had yet convinced him that the position ought to be taken as a *fait accompli*. To put forward any proposals without stressing that original source of the difficulty would be a mistake. If he had to choose between the proposals of the Committee and those of Colonel Rait he would favour the proposals of the Committee, because he did not believe it would be well to wait until the whole situation came up for review in four years' time, but some good might be done by a deputation, which would emphasize the trouble arising from the "transferred subject."
